THE ARCHITECTS' AND BUILDERS' HANDBOOK

THE ARCHITECTS' AND BUILDERS' HANDBOOK

DATA FOR
ARCHITECTS, STRUCTURAL ENGINEERS,
CONTRACTORS, AND DRAUGHTSMEN

BY

THE LATE FRANK E. KIDDER, C. E., PH. D.
AUTHOR OF "BUILDING CONSTRUCTION AND SUPERINTENDENCE"

COMPILED BY A STAFF OF SPECIALISTS AND
THOMAS NOLAN, M.S., A.M., EDITOR-IN-CHIEF
FELLOW OF THE AMERICAN INSTITUTE OF ARCHITECTS; PROFESSOR OF
ARCHITECTURAL CONSTRUCTION, UNIVERSITY OF PENNSYLVANIA

SEVENTEENTH EDITION, ENLARGED
TOTAL ISSUE, ONE-HUNDRED AND FIVE THOUSAND

NEW YORK
JOHN WILEY & SONS, Inc.
LONDON: CHAPMAN & HALL, LIMITED

The Publishers and the Editor-in-Chief will be grateful to readers of t
volume who will call attention to any errors of omission or commission there
It is intended to make our publications standard works of study and referen
and, to that end, the greatest accuracy is sought. It rarely happens that t
early editions of books are free from errors; but it is the endeavor of t
Publishers to have them removed, and it is therefore desired that the Edit
in-Chief may be aided in his task of revision, from time to time, by the kinc
criticism of readers.

* Dedication to First Edition.

EDITORIAL STAFF

NOTE TO SEVENTEENTH EDITION

WITH this edition the name is changed from Pocket-Book to Handbook
The work has been revised, some chapters rewritten, new chapters addec
and a new Index made. Many cuts have been reengraved.

The twenty-nine chapters of Part II have been revised where necessary t
make the data agree with the latest research and practice, and two new chapter
have been added, Chapter XXX, on Specifications for the Steelwork of Builc
ings, by Robins Fleming, and Chapter XXXI, on Domical and Vaulted Struc
tures, by Edward F. Ries. Chapter XXIII, on Fireproofing of Buildings, an
Chapter XXIV, on Reinforced-Concrete Construction, have been rewritten b
Rudolph P. Miller. In Part III, the sections on Heating and Ventilation, an
Chimney Construction, have been entirely rewritten by Louis A. Harding
The new chapters and sections include numerous practical examples of every
day problems, with solutions worked out in complete detail.

In addition to the new chapters, numerous new articles have been added t
the text and illustrations of Part II, on the following subjects: New Data o
Building Laws Relating to Loads on Masonry; Graphical Method of Determin
ing the Center of Gravity of Plane Figures or Sections; Graphical Method o
Determining Moments of Inertia of Plane Figures; Triangular Loading; Enc
Connections of Tension-Members; New Wire-Data; New Matter on Gauges
New Matter on Chains; Graphical Method of Determining the Deflection o
Beams; Secondary Stresses; Angles Used as Beams; Data on Girderless
Reinforced-Concrete Floors; Data on Tanks, and on Stresses in Cylindrical
Tanks, etc. Other revisions and additions have been made, including new
sections relating to the Registration of Architects, Standard Documents of the
American Institute of Architects, Architectural Education, etc.

In its revised, compact, and convenient form, the Editor believes that the work, more than ever before, will maintain its preeminence as the authoritative Handbook of Building-Construction.

PHILADELPHIA, July, 1921.

PREFACE TO SIXTEENTH EDITION

The changes in the fifteenth edition, published in 1908, consisted principally of the rewriting of the two chapters on Fireproofing of Buildings and Reinforced Concrete.

In 1912 the undersigned was asked to undertake the revision of the entire book with the cooperation of a corps of Associate Editors, each highly qualified to render the necessary assistance in matters pertaining to his own work. On account of the comprehensive nature of the contents of the Pocket-Book, the many recent changes and rapid developments in different fields of architectural construction, and the consequent effect of such changes on the interrelated subjects treated, the Editor-in-Chief decided to rewrite and reset the entire book. After more than three years of arduous labor, in which the Associate Editors and many other contributors have most ably and generously assisted, the New Kidder is about to be published.

It was decided to retain Mr. Kidder's original arrangement of the subject-matter which is divided into three Parts, Part I dealing with practical applications of Arithmetic, Geometry and Trigonometry, Part II with the Materials of Construction and the Strength and Stability of Structures, and Part III with miscellaneous useful information for architects and builders. Each of the twenty-nine chapters of Part II, however, has the name of the Associate Editor who revised or rewrote it printed with the chapter-caption. Part I has been carefully checked and much of the matter rearranged. The twenty-eight chapters of Part II have been rewritten and one new chapter has been added on Reinforced-Concrete Mill and Factory-Construction. Part III has been largely rewritten and all subjects retained have been thoroughly revised. To this part, also, much new matter has been added, such as extended tables of Specific Gravities and Weights of Substances, Architectural Acoustics, Waterproofing for Foundations, the Quantity System of Estimating, the Standard Documents of the American Institute of Architects, Educational Societies of the World and extended lists of Architectural Schools, Books and Periodicals.

The Editor-in-Chief has, with very few exceptions, personally checked on every page of manuscript, galley-proof and page-proof the equations, formulas, computations and problems, and has read or examined carefully every word, figure and illustration, every detail of syntax, paragraphing, punctuation and typography, and every arrangement of tables, captions, classifications, notation, Table of Contents and Index.

He is responsible for many changes in the form of presentation of data which it is hoped will add to the Pocket-Book still more of that efficiency and practical usefulness for which it has been so long noted. Some of these changes may be briefly mentioned. The text has been entirely reset; the type, while slightly smaller, is clearer and has the lines and paragraphs separated by wide leads; a special type is used for the tables; the paragraphing is revised throughout and every paragraph has a black-face type caption descriptive of the subject-matter; words in italics or with quotation-marks are seldom used, words in small caps taking their place; every chapter is divided into numbered chapter-subdivisions which are briefly descriptive of the classified matter; the number of cross-

references is largely increased and the page-numbers of such references are alm always added; many tables and diagrams which in the former editions r lengthwise of the page have been reset or reengraved to read across the page greater convenience; the number of illustrations has been largely increased, ma old cuts reused have been reengraved, and some diagrams printed with lines different colors to make the demonstrations clearer; a descriptive caption l been added to every illustration; the abbreviations Chap. I, Chap. II, etc., ha been printed with each page-caption of the left-hand pages, thus avoiding t necessity of referring to the Table of Contents to locate any particular chapt

The Editor-in-Chief decided to change some of the unit stresses, especia those for the different woods, and in some cases to recommend more conservat values, and he believes that results based upon such stresses conform to the b engineering practice. This change necessitated the revision of many tables a problems throughout the book which had to be entirely recalculated. Num ous practical problems with complete solutions have been added. The deri tion of many of the formulas used has been explained, either in the body of t text or in extended foot-notes, for those who wish to understand as well as to u such formulas, and numerous cross-references accompanying them enable t reader to use the Pocket-Book as a textbook for certain parts of the mechan of materials as well as a handbook for office work. The tables of the propert of structural shapes, of safe loads for columns, beams and girders, etc., have be revised and numerous new tables added. The Editor has found that it is the co sensus of opinion among architects that the insertion of these tables is a gre convenience and for their ordinary office work condenses into one handy v ume much of the essential data of several manufacturers' handbooks.

The difficulty of securing a unity of treatment and of avoiding repetitions a contradictions in a book of reference the data of which covers so many subje and is written by so many contributors has been fully realized; but it is believ that in these respects the New Kidder is reasonably successful and will me with the approval of all who use it.

Acknowledgments and thanks are due the Associate Editors for their hear cooperation and generous contributions of the time and labor taken from th professional work. Acknowledgment is made, also, of the valuable assistan of all others who have furnished new or revised old data, and of many helpf suggestions from Mrs. F. E. Kidder and from the publishers.

The Editor-in-Chief expresses the hope that for the architects and builde of this country the new Pocket-Book will continue to be, as Mr. Kidder express it in his preface to the first edition in 1884, "a compendium of practical fact rules and tables presented in a form as convenient for application as possibl and as reliable as our present knowledge will permit;" and also, in its prese extension and fuller development, a work which will lead to a still clearer unde standing of the essential principles of sound architectural construction.

THOMAS NOLAN.

PHILADELPHIA, September, 1915.

PREFACE TO FOURTEENTH EDITION

It is now nearly twenty years since the author, then quite a young man, completed the first edition of this work, which, although containing but 586 pages, had required about three years for its preparation. At that time the author thought he had covered all of those practical details relating to the planning and construction of buildings, with which the architect was concerned, reasonably well, and it would appear as though the purchasers of the book thought so too, but as the years have come and gone, so many and such great improvements have taken place in the building world, so many articles invented, new methods of construction developed, higher standards established, that the present edition, although containing nearly three times as many pages, is perhaps not more complete, for the times, than was the first edition.

When preparing the first edition, it was the aim of the author to give to architects and builders a handbook which should be, in its field, as useful and reliable as Trautwine's had been to civil engineers; and with that object constantly in view, the book has been revised from time to time to meet the changed conditions in building construction and equipment.

About three years ago it was thought, by the publishers and the author, that a thorough and complete revision of the book should be undertaken, and although the re-writing of a work of this character, even with the thirteenth edition to work from, involved many months of close and constant application, the utilization of those hours which one ordinarily takes for recreation, and at the best more or less interruption to his regular business, and consequent reduction in income, the writer undertook to prepare a work of a still wider scope, and which should be thoroughly up-to-date in every particular, or at least as far as is practicable, in a work requiring a period of three years in its preparation, and from that time to this he has spared no labor or expense to make the book as useful and complete as he possibly could, without making it too bulky.

In this revision the author has had in view:

1st. A reference-book which should contain some information on every subject (except design) likely to come before an architect, structural engineer, draughtsman or master-builder, including data for estimating the approximate cost.

2d. To as thoroughly cover the subject of architectural engineering as is practicable in a handbook.

3d. To present all information in as simple and convenient a form for immediate application as is consistent with accuracy. To this end a great many new tables, arranged and computed by the author, have been inserted.

At the time the first edition was written, the term "Architectural Engineering" had not been used in its present application, and the term "Structural Engineering," when used, referred almost exclusively to bridge work.

To-day, structural and architectural engineers are concerned almost exclusively with building construction, and their work is more closely allied to that of the architect than to that of the civil engineer; hence the author has had in mind the needs of the structural engineer and draughtsman as well as those of the architect and builder, and the book should be of nearly equal value to both.

Where it was impossible, for lack of space, to go extensively into any sub references to other books or sources of information have been given, so tha this way the book may serve as a general index to the many lines of w materials, and manufactured products entering into the planning, construc and equipment of buildings.

To attain the objects in view, it has been necessary to add considerably tc number of pages, but as experience has shown that the book is used princip at the desk or draughting-table, and is seldom carried in the pocket, it is beli that the convenience of having everything in one book will more than offset disadvantage resulting from increase in bulk.

Nearly the entire book has been re-written, and great pains have been ta to furnish reliable data. A large number of experts in various lines have assi the author, as is manifest by the foot-notes and references. To all of such, to the many authors of technical works, and to the publishers of techn journals, who have kindly consented to the use of cuts and data, the aut takes pleasure in acknowledging his indebtedness. Also to Mr. E. S. Hand New York, who, for many years, has rendered material assistance in collec data along the line of manufactured products.

The names and addresses of manufacturers have been given solely for convenience of the users of the book, and not for any pecuniary considerati in fact, if money considerations had solely appealed to the writer, this book wc never have been re-written, because a technical work of this character can ne adequately compensate, in money, for the time, labor, and thought require its preparation. The many words of appreciation which have come to the aut from hundreds of those who have found the book useful have been a gr stimulus to further increase its usefulness.

As in the former prefaces, the author requests that any one discovering err in the work or who may have any suggestions looking to the further impro ment of the book, will communicate the same to him, that the book may be m as complete and reliable as possible.

Finally, the author desires to acknowledge his indebtedness to the publish who have heartily seconded his efforts in every particular, and who have spa no pains or expense to make a perfect handbook.

PRACTICAL
RITHMETIC, GEOMETRY AND TRIGONOMETRY

RULES, TABLES AND PROBLEMS

1. PRACTICAL ARITHMETIC

Mathematical Signs and Characters*

The following signs and characters are generally used to denote and abbreviate the several mathematical operations:

The sign = means equal to, or equality;
− means minus or less, or subtraction;
+ means plus, or addition;
× means multiplied by, or multiplication;
÷ or / means divided by, or division;
² ³ are indexes or powers, meaning that the number to which they are added is to be squared (²) or cubed (³);
: is to, : : so is, : to are signs of proportion;
√ is the RADICAL SIGN and means that the square root of the number before which it is placed is to be extracted;
∛ means that the cube root of the number before which it is placed is to be extracted;
—— the BAR indicates that all the numbers under it are to be taken together;
( ) the PARENTHESIS means that all the numbers between are to be taken as one quantity;
. means decimal parts; thus, 2.5 means $2\frac{5}{10}$, 0.46 means $\frac{46}{100}$.
° means degrees, ′ minutes and ″ seconds;
∴ means hence;
′ means feet;
″ means inches.

Involution

To Square a Number, multiply the number by itself, and the product will be the square; thus, the square of 18 = $18^2 = 18 \times 18 = 324$.

The Cube of a Number is the product obtained by multiplying the number by itself, and that product by the number again; thus, the cube of 14 = $14^3 = 14 \times 14 \times 14 = 2\,744$.

The Fourth Power of a Number is the product obtained by multiplying the number by itself four times; thus, the fourth power of 10 = $10^4 = 10 \times 10 \times 10 \times 10 = 10\,000$.

Evolution

Square Root. Rule for extracting the square root of a number:

(1) Divide the given number into periods of two figures each, commencing at the right if it is a whole number, and at the decimal point if there are decimals; thus, $1\dot{0}2\dot{3}6.\dot{8}1\dot{2}6$.

(2) Find the largest square in the left-hand period, and place its root in the quotient; subtract the said square from the left-hand period, and to the remainder bring down the next period for a new dividend.

(3) Double the root already found, and annex one cipher for a trial-divisor; see how many times it will go in the dividend, and put the number in the quotient

* See, also, pages 122 and 123, Part II.

and also in place of the cipher in the divisor. Multiply this final divisor by the number in the quotient just found, subtract the product from the dividend and to the remainder bring down the next period for a new dividend and proceed as before. If it should be found that the trial divisor cannot be contained in the dividend, bring down the next period for a new dividend, annex another cipher to the trial divisor, put a cipher in the quotient and proceed as before.

Example.

```
             10236.8126 (101.17, the square root
          1
     201)0236
          201
    2021)3581
         2021
   20227)156026
         141589
          14437
```

Cube Root. To extract the cube root of a number, point off the number from right to left into periods of three figures each, and, if there is a decimal, commence at the decimal point and point off into periods, going both ways.

Ascertain the highest root of the first period, and place it to the right of the number, as in long division; cube the root thus found and subtract from the first period; to the remainder annex the next period; square the root already found, multiply by three and annex two ciphers for the trial divisor. Find how many times this trial divisor is contained in the dividend and write the result in the root.

Add together the trial divisor, three times the product of the first figure of the root by the second with one cipher annexed, and the square of the second figure in the root; multiply the sum by the last figure in the root, and subtract from the dividend; to the remainder annex the next period and proceed as before.

When the trial divisor is greater than the dividend, write a cipher in the root, annex the next period to the dividend and proceed as before.

Example. Required, the cube root of 493039 or $\sqrt[3]{493039}$

```
                        493039(79, the cube root
           7×7×7 =      343
         7×7×3 = 14700 | 150039
         7×9×3 =  1890 |
           9×9 =    81 |
                 16671 | 150039
```

Example. Required, the cube root of 403583.419 or $\sqrt[3]{403583.419}$

```
                           403583.419(73.9, the cube root
               7×7×7 =     343
             7×7×3 = 14700    | 60583
             7×3×3 =   630    |
               3×3 =     9    |
                     15339    | 46017
        73×73×3 = 1598700     | 14566419
        73× 9×3 =   19710     |
            9×9 =      81     |
                  1618491     | 14566419
```

Example. Required, the cube root of 158252.632929 or $\sqrt[3]{158252.632929}$

```
                                 158252.632929(54.09, the cube root
                5 × 5 × 5 = 125
           5 × 5 × 3 = 7500 | 33252
           5 × 4 × 3 =  600 |
               4 × 4 =   16 |
                       8116 | 32464
 540 × 540 × 3 = 87480000   |   788632929
 540 ×   9 × 3 =   145800   |
         9 × 9 =       81   |
                 87625881   |   788632929
```

TABLES

OF

SQUARES, CUBES, SQUARE ROOTS, CUBE ROOTS AND RECIPROCALS

From 1 to 1054

The following table, taken from Searle's Field Engineering, will be found of great convenience in finding the square, cube, square root, cube root and reciprocal of any number from 1 to 1054. The reciprocal of a number is the quotient obtained by dividing 1 by the number. Thus, the reciprocal of 8 is $1 \div 8 = 0.125$.

No.	Squares	Cubes	Square roots	Cube roots	Reciprocals

2. WEIGHTS AND MEASURES

Measures of Length

= 1 foot
= 1 yard = 36 inches
= 1 rod = 198 inches = 16½ feet
= 1 furlong = 7 920 inches = 660 feet = 220 yards
= 1 mile = 63 360 inches = 5 280 feet = 1 760 yards = 320 rods
= 0.0000158 of a mile

Gunter's Chain

7.92 inches = 1 link
100 links = 1 chain = 4 rods = 66 feet
80 chains = 1 mile

Ropes and Cables

6 feet = 1 fathom   120 fathoms = 1 cable's length

Table Showing Inches Expressed in Decimals of a Foot

Nautical Measures

A nautical or sea-mile is the length of a minute of longitude of the ear he equator at the level of the sea. It is assumed that 6086.07 ft = 1.1 tatute or land-miles by the United States Coast Survey.

3 nautical miles = 1 league

Miscellaneous Measures

1 palm = 3 inches	1 span = 9 inches
1 hand = 4 inches	1 meter = 3.2809 feet

Measures of Surface

144 square inches = 1 square foot
9 square feet = 1 square yard = 1 296 square inches
100 square feet = 1 square (architects' measure)

Land Measure

30¼ square yards = 1 square rod
40 square rods = 1 square rood = 1 210 square yards
4 square roods = 1 acre = 4 840 square yards
10 square chains = 160 square rods
640 acres = 1 square mile = 3 097 600 square yards =
2 560 square roods
208.71 feet square = 1 acre = 43560 square feet

A section of land is a square mile, and a QUARTER-SECTION is 160 acres

Measures of Volume

A gallon, liquid measure = 231 cubic inches, and contains 8.339 avoirdupois pounds of distilled water at 39.8° F., or 58 333 grains
A cubic foot contains 7.48 liquid gallons, or 6.428 dry gallons
A gallon, dry measure = 268.8 cubic inches
A bushel (Winchester) contains 2150.42 cubic inches, or 77.627 pounds distilled water at 39.8° F.
A heaped bushel contains 2747.715 cubic inches

Dry Measure

2 pints = 1 quart = 67.2 cubic inches
4 quarts = 1 gallon = 8 pints = 268.8 cubic inches
2 gallons = 1 peck = 16 pints = 8 quarts = 537.6 cubic inches
4 pecks = 1 bushel = 64 pints = 32 quarts = 8 gallons
= 2150.42 cubic inches
1 cord of wood = 128 cubic feet

Liquid Measure

4 gills = 1 pint = 16 fluid ounces
2 pints = 1 quart = 8 gills = 32 fluid ounces
4 quarts = 1 gallon = 32 gills = 8 pints = 128 fluid ounces

In the United States and Great Britain 1 barrel of wine or brandy = 31½ gallons, and contains 4.211 cubic feet.
A hogshead is 63 gallons, but this term is often applied to casks of various capacities.

Cubic Measure

1728 cubic inches = 1 cubic foot
27 cubic feet = 1 cubic yard

In MEASURING WOOD, a pile of wood cut 4 feet long, piled 4 feet high, and 8 feet on the ground, making 128 cubic feet, is called a CORD.
16 cubic feet make one cord-foot.
A PERCH OF STONE is nominally 16½ feet long, 1 foot high and 1½ feet thick, and contains 24¾ cubic feet.

A perch of stone is, however, often computed differently in different l thus, in most if not all of the States and Territories west of the Mi stone-masons figure rubble by the perch of 16½ cubic feet. In Phil 22 cubic feet are called a perch. In Chicago, stone is measured by th 100 cubic feet.

A TON of shipping is 42 cubic feet in Great Britain and 40 cubic fe United States.

Fluid Measure

60 minims	= 1 fluid drachm
8 fluid drachms	= 1 ounce
16 ounces	= 1 pint
8 pints	= 1 gallon

Miscellaneous Measures

Butt of Sherry	= 108 gallons	Puncheon of Brandy	= 110 to 120
Pipe of Port	= 115 gallons	Puncheon of Rum	= 100 to 110
Butt of Malaga	= 105 gallons	Hogshead of Brandy	= 55 to 60
Puncheon of Scotch Whiskey,	= 110 to 130 gallons	Hogshead of Claret	= 46 gallons

Measures of Weight

The standard AVOIRDUPOIS POUND is the weight of 27.7015 cubic i distilled water weighed in air at 39.83° F., with the barometer at 30 It contains 7 000 grains. One pound avoirdupois = 1.2153 pounds troy

Avoirdupois, or Ordinary Commercial Weight

1 drachm	= 27.343 grains	
16 drachms	= 1 ounce	(oz)
16 ounces	= 1 pound	(lb)
100 pounds	= 1 hundredweight	(cwt)
20 hundredweight	= 1 ton	

In collecting duties upon foreign goods at the United States custom- and also in freighting coal and selling it by wholesale,

28 pounds	= 1 quarter
4 quarters, or 112 pounds	= 1 hundredweight
20 hundredweight	= 1 long ton = 2 240 pounds.
A stone	= 14 pounds
A quintal	= 100 pounds

The following measures are sanctioned by custom or law: 1 bushel = cubic feet or 1¼ cubic feet, nearly.

32 pounds of oats	= 1 bushel
45 pounds of Timothy-seed	= 1 bushel
48 pounds of barley	= 1 bushel
56 pounds of rye	= 1 bushel
56 pounds of Indian corn	= 1 bushel
50 pounds of Indian meal	= 1 bushel
60 pounds of wheat	= 1 bushel
60 pounds of clover-seed	= 1 bushel
60 pounds of potatoes	= 1 bushel

56 pounds of butter	= 1 firkin
100 pounds of meal or flour	= 1 sack
100 pounds of grain or flour	= 1 cental
100 pounds of dry fish	= 1 quintal
100 pounds of nails	= 1 cask
196 pounds of flour	= 1 barrel
200 pounds of beef or pork	= 1 barrel
80 pounds of lime	= 1 bushel

Troy Weight

Used in Weighing Gold or Silver

24 grains	= 1 pennyweight	(pwt)
20 pennyweights	= 1 ounce	(oz)
12 ounces	= 1 pound	(lb)

arat of the jewelers, for precious stones, is, in the United States, 3.2 s, but it varies according to different authorities. In London, 3.17 grains, is, 3.18 grains are divided into 4 jewelers' grains. The international is 3.168 grains or 200 milligrams. In troy, apothecaries' and avoirdupois ts, the grain is the same, 1 pound troy being equal to 0.82286 pound dupois.

Apothecaries' Weight

Used in Compounding Medicines and in Putting Up Medical Prescriptions

20 grains (gr)	= 1 scruple (℈)	8 drachms	= 1 ounce (oz)
3 scruples	= 1 drachm (ʒ)	12 ounces	= 1 pound (lb)

Measures of Value

United States Standard

10 mills	= 1 cent	10 dimes	= 1 dollar
10 cents	= 1 dime	10 dollars	= 1 eagle

e standard of gold and silver is 900 parts of pure metal and 100 of alloy 00 parts of coin.
e fineness expresses the quantity of pure metal in 1 000 parts.
e remedy of the mint is the allowance for deviation from the exact standness and weight of coins.

Weights of Coins

Double eagle	= 516	troy grains
Eagle	= 258	troy grains
Dollar (gold)	= 25.8	troy grains
Dollar (silver)	= 412.5	troy grains
Half-dollar	= 192	troy grains
5-cent piece (nickel)	= 77.16	troy grains
3-cent piece (nickel)	= 30	troy grains
Cent (bronze)	= 48	troy grains

Measures of Time

60 seconds	= 1 minute	365 days	= 1 common year
60 minutes	= 1 hour	366 days	= 1 leap-year
24 hours	= 1 day		

A SOLAR DAY is measured by the rotation of the earth upon its axis, with to the sun.

In ASTRONOMICAL COMPUTATIONS and in NAUTICAL TIME the day comme noon, and in the former it is counted throughout the 24 hours.

In CIVIL COMPUTATIONS the day commences at midnight, and is divid two parts of 12 hours each.

A SOLAR YEAR is the time in which the earth makes one revolution aro sun. Its average time, called the MEAN SOLAR YEAR, is 365 days, 5 48 minutes and 49.7 seconds, or nearly 365¼ days.

A MEAN LUNAR MONTH, or LUNATION of the moon, is 29 days, 12 hours, utes, 2 seconds and 5.24 thirds. It is equal, on the average, to 29.53 day

The Calendar, Old and New Style

The JULIAN Calendar was established by Julius Cæsar, 44 B.C., and by day was inserted in every fourth year. This was the same thing as as that the length of the solar year was 365 days and 6 hours, instead of th given above, thus introducing an accumulative error of 11 minutes and onds every year. This calendar was adopted by the church in 325 A.D., Council of Nice. In the year 1582 the annual error of 11 minutes and 12 s had amounted to 10 days, which, by order of Pope Gregory XIII, was supp in the calendar, and the 5th of October reckoned as the 15th. To preve repetition of this error, it was decided to leave out three of the inserte every 400 years, and to make this omission in the years which are not divisible by 400. Thus, of the years 1700, 1800, 1900 and 2000, all of are leap-years according to the Julian Calendar, only the last is a lea according to the REFORMED or GREGORIAN Calendar. This Reformed Ca was not adopted by England until 1752, when 11 days were omitted fr calendar. The two calendars are now often called the OLD STYLE and th STYLE. The latter style is now adopted in every Christian country Russia.

Circular and Angular Measures

USED FOR MEASURING ANGLES AND ARCS, AND FOR DETERMINING L TUDE AND LONGITUDE

60 seconds (″)	= 1 minute	(′)
60 minutes	= 1 degree	(°)
360 degrees	= 1 circumference	(C)

The SECOND is usually subdivided into tenths and hundredths.

A MINUTE of the circumference of the earth is a geographical mile.

The DEGREES of the earth's circumference on a meridian average 69.16 mon miles.

The Metric System

The METRIC SYSTEM is a system of weights and measures based upon called a METER.

The METER was intended to be one ten-millionth part of the distance fro equator to either pole, measured on the earth's surface at the level of the se

names of derived metric denominations are formed by prefixing to the of the primary unit of measure:

Milli, a thousandth	Hecto, one hundred
Centi, a hundredth	Kilo, a thousand
Deci, a tenth	Myria, ten thousand
Deca, ten	

system, first adopted by France, has been extensively adopted by other ies, and is much used in the sciences and the arts. It was legalized in by Congress to be used in the United States, and is already employed by Coast Survey, and, to some extent, by the Mint and the General Post-

Linear Measures

METER is the primary unit of lengths.

10 millimeters (mm)	= 1 centimeter (cm)	= 0.3937 inch
10 centimeters	= 1 decimeter (dm)	= 3.937 inches
10 decimeters	= 1 METER (m)	= 39.37 inches
10 meters	= 1 decameter	= 393.37 inches
10 decameters	= 1 hectometer	= 328 feet 1 inch
10 hectometers	= 1 KILOMETER (km)	= 0.62137 mile
10 kilometers	= 1 myriameter	= 6.2137 miles

METER is used in ordinary measurements; the CENTIMETER, or MILLI-, in reckoning very small distances; and the KILOMETER, for roads or distances.

CENTIMETER is about 2/5 of an inch; a METER is about 3 feet 3 3/8 inches; a METER is about 200 rods, or 5/8 of a mile. (See page 33.)

Measures of Surface

SQUARE METER is the primary unit of ordinary surfaces.

ARE, a square, each of whose sides is ten METERS, is the unit of land res.

100 square millimeters (mm^2) = 1 square centimeter (cm^2) = 0.155 square inch
100 square centimeters = 1 square decimeter = 15.5 square inches
100 square decimeters = 1 square METER (m^2) = 1 550 square inches, or 1.196 square yards

100 centiares, or square meters	= 1 ARE (a)	= 119.6 square yards
100 ares	= 1 hectare (ha)	= 2.471 acres

SQUARE METER, or one CENTIARE, is about 10 3/4 square feet, or 1 1/5 square s, and a HECTARE is about 2 1/2 acres.

Cubic Measure

CUBIC METER, or STERE, is the primary unit of a volume.

1000 cubic millimeters (mm^3) = 1 cubic centimeter (cm^3) = 0.061 cubic inch
1000 cubic centimeters = 1 cubic decimeter (dm^3) = 61.022 cubic inches
1000 cubic decimeters = 1 cubic METER (m^3) = 35.314 cubic feet

STERE is the name given to the cubic meter in measuring wood and timber. th of a stere is a DECISTERE, and ten steres are a DECASTERE.

CUBIC METER, or STERE, is about 1 1/3 cubic yards, or about 2 1/5 cord feet.

Liquid and Dry Measures

The LITER is the primary unit of measures of capacity, and is a cube, whose edges is a tenth of a meter in length.

The HECTOLITER is the unit in measuring large quantities of grain roots and liquids.

10 milliliters (ml)	= 1 centiliter (cl)	= 0.338 fluid ounce
10 centiliters	= 1 deciliter	= 0.845 liquid gill
10 deciliters	= 1 LITER (l)	= 1.0567 liquid quarts
10 liters	= 1 decaliter	= 2.6417 gallons
10 decaliters	= 1 HECTOLITER (hl)	= 2 bushels, 3.35 pecks
10 hectoliters	= 1 kiloliter	= 28 bushels, 1½ pecks

A CENTILITER is about 1/3 of a fluid ounce; a LITER is about 1 1/16 liquid or 9/10 of a dry quart; a HECTOLITER is about 2 5/6 bushels; and a KILO one cubic meter, or stere.

Weights

The GRAM is the primary unit of weights, and is the weight in a vacu cubic centimeter of distilled water at the temperature of 39.2° F.

10 milligrams (mg)	= 1 centigram (cg)	=	0.1543 troy grain
10 centigrams	= 1 decigram (dg)	=	1.543 troy grains
10 decigrams	= 1 GRAM (g)	=	15.432 troy grains
10 grams	= 1 decagram	=	0.3527 avoirdupois oun
10 decagrams	= 1 hectogram	=	3.5274 avoirdupois oun
10 hectograms	= 1 KILOGRAM (kg)	=	2.2046 avoirdupois pou
10 kilograms	= 1 myriagram	=	22.046 avoirdupois pou
10 myriagrams	= 1 quintal (q)	=	220.46 avoirdupois pou
10 quintals	= 1 TONNEAU (t)	=	2204.6 avoirdupois pou

1 kilogram per kilometer = 0.67195 pound per 1 000 feet
1 pound per thousand feet = 1.4882 kilograms per kilometer
1 kilogram per square millimeter = 1 423 pounds per square inch
1 pound per square inch = 0.000743 kilogram per square millimeter

The GRAM is used in weighing gold, jewels, letters and small quanti things. The KILOGRAM, or, for brevity, KILO, is used by grocers; a TONNEAU, or METRIC TON, is used in finding the weight of very heavy artic

A GRAM is about 15½ grains troy; the KILO about 2 1/5 pounds avoird and the METRIC TON, about 2 205 pounds.

A KILO is the weight of a liter of water at its greatest density; and the TON, of a cubic meter of water.

Metric numbers are written with the decimal point (.) at the right figures denoting the unit; thus the expression, 15 meters 3 centimet written, 15.03 m.

When metric numbers are expressed by figures, the part of the express the left of the decimal point is read as the number of the unit, and the p the right, if any, as a number of the lowest denomination indicated, o decimal part of the unit; thus, 46.525 m is read 46 meters and 525 millim or 46 and 525 thousandths meters.

In writing and reading metric numbers, according as the scale is 10, 1 000, each denomination should be allowed one, two or three orders of fi

Metric Conversion Table

The following metric conversion table has been compiled by C. W. and is most convenient in dealing with metric weights and measures:

Millimeters × 0.03937	= inches
Millimeters ÷ 25.4	= inches
Centimeters × 0.3937	= inches
Centimeters ÷ 2.54	= inches
Meters × 39.37	= inches (Act of Congress)
Meters × 3.281	= feet
Meters × 1.094	= yards
Kilometers × 0.621	= miles
Kilometers ÷ 1.6093	= miles
Kilometers × 3280.7	= feet
Square millimeters × 0.0155	= square inches
Square millimeters ÷ 645.1	= square inches
Square centimeters × 0.155	= square inches
Square centimeters ÷ 6.451	= square inches
Square meters × 10.764	= square feet
Square kilometers × 247.1	= acres
Hectares × 2.471	= acres
Cubic centimeters ÷ 16.383	= cubic inches
Cubic centimeters ÷ 3.69	= fluid drachms (U.S. Pharmacopœia)
Cubic centimeters ÷ 29.57	= fluid ounce. (U.S. Pharmacopœia)
Cubic meters × 35.315	= cubic feet
Cubic meters × 1.308	= cubic yards
Cubic meters × 264.2	= gallons (231 cubic inches)
Liters × 61.022	= cubic inches. (Act of Congress)
Liters × 33.84	= fluid ounces. (U.S. Pharmacopœia)
Liters × 0.2642	= gallons (231 cubic inches)
Liters ÷ 3.78	= gallons (231 cubic inches)
Liters ÷ 28.316	= cubic feet
Hectoliters × 3.531	= cubic feet
Hectoliters × 2.84	= bushels (2 150.42 cubic inches)
Hectoliters × 0.131	= cubic yards
Hectoliters × 26.42	= gallons (231 cubic inches)
Grams × 15.432	= grains. (Act of Congress)
Grams × 981	= dynes
Grams (water) ÷ 29.57	= fluid ounces
Grams ÷ 28.35	= ounces avoirdupois
Grams per cubic centimeter ÷ 27.7	= pounds per cubic inch
Joule × 0.7373	= foot-pounds
Kilograms × 2.2046	= pounds
Kilograms × 35.3	= ounces avoirdupois
Kilograms ÷ 1102.3	= tons (2 000 pounds)
Kilograms per sq cm × 14.223	= pounds per square inch
Kilogrammeters × 7.233	= foot-pounds
Kilograms per meter × 0.672	= pounds per square foot
Kilograms per cubic meter × 0.062	= pounds per cubic foot
Kilograms per cheval-vapeur × 2.235	= pounds per horse-power
Kilowatts × 1.34	= horse-power
Watts ÷ 746	= horse-power
Watts × 0.7373	= foot-pounds per second
Calorie × 3.968	= British thermal units (B.T.U.)
Cheval-vapeur × 0.9863	= horse-power
(Centigrade × 1.8) + 32	= degrees Fahrenheit
Francs × 0.193	= dollars
Gravity, Paris	= 980.94 centimeter per second

Metric Conversion Tables. This and the following table fr
worth's Metrical Tables will be found of great convenience in figu
to be executed in Mexico and other countries using the metric syste

3. GEOMETRY AND MENSURATION

Definitions

A POINT is that which has only position.

A PLANE is a surface in which, any two points being taken, the st joining them will be wholly in the surface.

A CURVED LINE is a line of which no part is straight (Fig. 1).

Fig. 1. Curved Line

Fig. 2. Parallel Lines

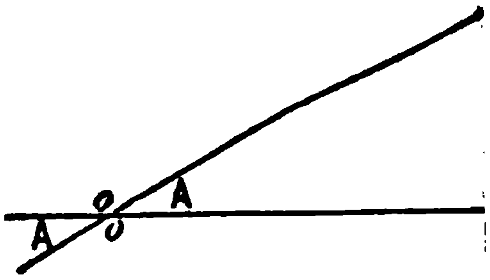

Fig. 3. Angles

PARALLEL LINES are such as are wholly in the same plane, and have direction (Fig. 2).

A BROKEN LINE is a line composed of a series of dashes; thus, —— –

An ANGLE is the opening between two lines meeting at a point, and a RIGHT ANGLE when the two lines are perpendicular to each other, ANGLE when it is less or sharper than a right angle, and an OBTUSE AN it is greater than a right angle. Thus, in Fig. 3,

A A A A are ACUTE ANGLES,

o o o o are OBTUSE ANGLES and *R R R R* are RIGHT ANGLES.

Polygons

A POLYGON is a portion of a plane bounded by straight lines.

A TRIANGLE is a polygon of three sides.

A SCALENE TRIANGLE has none of its sides equal; an ISOSCELES TRIA two of its sides equal; an EQUILATERAL TRIANGLE has all three of its sid

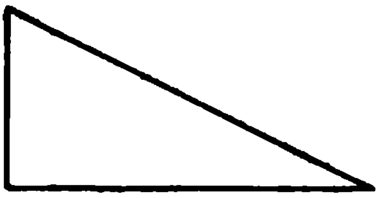

Fig. 4. Right-angled Triangle

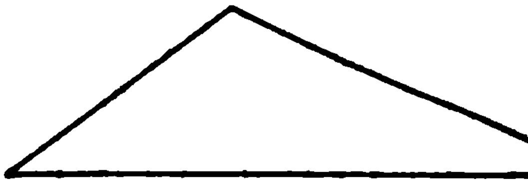

Fig. 5. Scalene Triangle

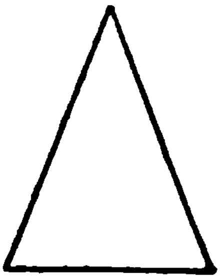

Fig. 6. Isosceles Triangle

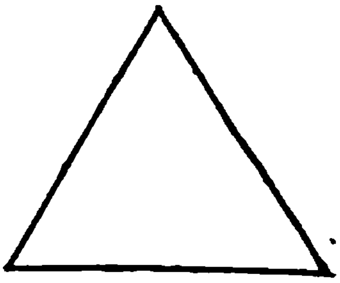

Fig. 7. Equilateral Tria

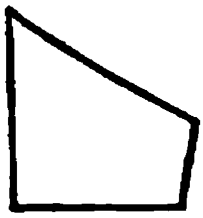
A RIGHT-ANGLED TRIANGLE is one which has a right angle. The side the right angle is called the HYPOTHENUSE; the side on which the t supposed to stand is called its BASE and the other side, its ALTITUDE.

...ADRILATERAL is a polygon of four sides.

...drilaterals are divided into classes, as follows: the TRAPEZIUM (Fig. 8), ...h has no two of its sides parallel; the TRAPEZOID (Fig. 9), which has two of ...des parallel; and the PARALLELOGRAM (Fig. 10), which is bounded by two ...of parallel sides.



...ig. 8. Trapezium

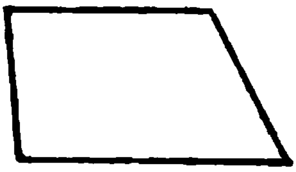


Fig. 9. Trapezoid

Fig. 10. Parallelogram

...parallelogram whose sides are not equal and whose angles are not right ...s is called a RHOMBOID (Fig. 11); when the sides are all equal, but the ...s are not right angles, it is called a RHOMBUS (Fig. 12), and when the angles ...right angles, it is called a RECTANGLE (Fig. 13). A rectangle, all of whose ...s are equal, is called a SQUARE (Fig. 14). Polygons, all of whose sides are ...l, are called REGULAR POLYGONS.

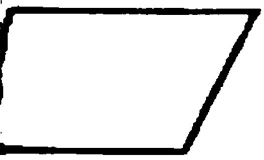

Fig. 11.

Hexagon

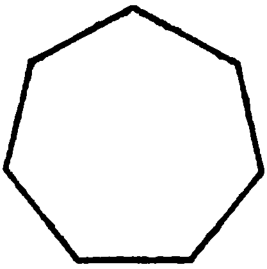

Fig. 17.
Heptagon

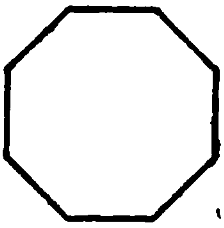

Fig. 18.
Octagon

...he ENNEAGON or NONAGON has nine sides; the DECAGON has ten sides; and ...ODECAGON has twelve sides.

...or all polygons, the side upon which it is supposed to stand is called its ...e; the perpendicular distance from the highest side or angle to the base ...longed, if necessary) is called the ALTITUDE; and a line joining any two ...es not adjacent is called a DIAGONAL.

...PERIMETER is the bounding line of a plane figure.

...CIRCLE is a portion of a plane bounded by a curve, all the points of which ...equidistant from a point within, called the CENTER (Fig. 19).

...he CIRCUMFERENCE is the curve which bounds the circle.

...RADIUS is any straight line drawn from the center to the circumference.

...y straight line drawn through the center to the circumference on each side ...led a DIAMETER.

An ARC of a circle is any part of its circumference.

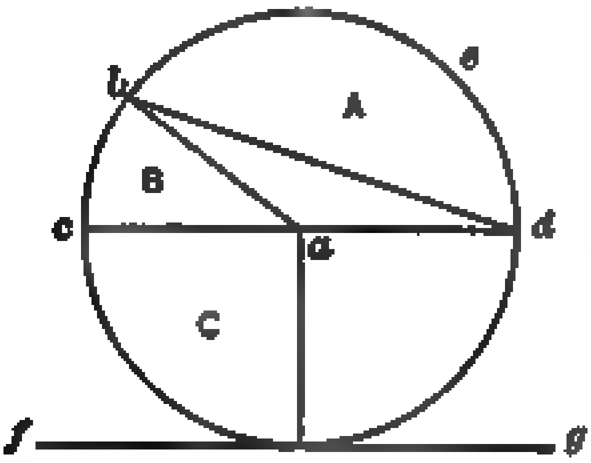

Fig. 19. Circle and Parts

A CHORD is any straight line joi[ning two] points of the circumference, as *bd*, [...]

A SEGMENT is a portion of th[e circle] included between the arc and its c[hord, as] *A*, Fig. 19.

A SECTOR is the space included [between] an arc and two radii drawn to [its ex]tremities, as *B*, Fig. 19. In the fi[gure, *ab*] is a radius, *cd* a diameter and *db* a [chord] SUBTENDING the arc *bed*. A TANG[ENT is a] right line which in passing a curve t[ouches it] without cutting it, as *fg*, Fig. 19.

Volumes

A PRISM is a volume whose ends are equal and parallel polygons and sides are parallelograms.

A prism is TRIANGULAR, RECTANGULAR, etc., according as its ends a[re TRI]ANGLES, RECTANGLES, etc.

A CUBE is a rectangular prism all of whose sides are squares.

A CYLINDER is a volume of uniform diameter, bounded by a curved [surface] and two equal and opposite parallel circles.

A PYRAMID is a volume whose base is a polygon and whose sides are t[riangles] meeting in a point called the VERTEX. A pyramid is triangular, quadra[ngular,] etc., according as its base is a triangle, quadrilateral, etc.

A CONE is a volume whose base is a circle, from which the remaining surface tapers uniformly to a point or vertex (Fig. 20).

A CONIC SECTION is the plane figure made by a plane cutting a cone.

An ELLIPSE is the section of a cone cut by a plane passing obliquely through both sides, as at *ab*, Fig. 21.

A PARABOLA is a section of a cone cut by a plane parallel to its side, as at *cd*.

Fig. 20. Cone

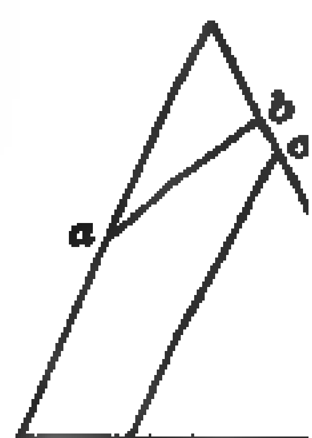

Fig. 21. Cone with Sectio[ns]

A HYPERBOLA is a section of a cone cut by a plane making a greate[r angle] with the base than that made by the side of the cone, as at *eh*.

In the ellipse, the TRANSVERSE AXIS, or LONG DIAMETER, is the longe[st line] that can be drawn in it The CONJUGATE AXIS, or SHORT DIAMETER, is [the line] drawn through the center at right-angles to the long diameter.

A FRUSTUM OF A PYRAMID or CONE is that which remains after cutting [off the] upper part of it by a plane parallel to the base.

A SPHERE is a volume bounded by a curved surface, all points of whi[ch are] equidistant from a point within, called the center.

Mensuration treats of the measurement of lines, surfaces and volum[es].

Rules

To compute the area of a square, a rectangle, a rhombus or a rhomboid.

Rule. Multiply the length by the breadth or height. Thus, in Figs. [...] or 24, the area = $ab \times bc$.

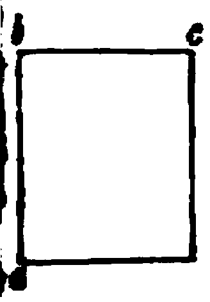

Fig. 22. Square

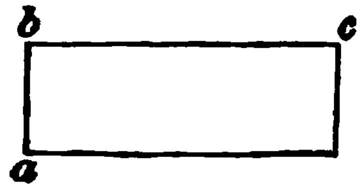

Fig. 23. Rectangle

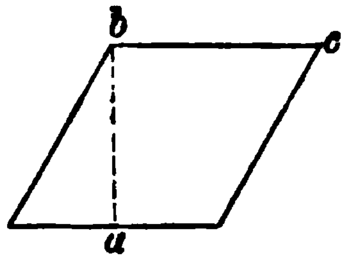

Fig. 24. Parallelogram

compute the area of a triangle.

le. Multiply the base by the altitude and divide by 2. Thus, in Fig. 25, area of $abc = \dfrac{ab \times cd}{2}$.

find the length of the hypothenuse of a right-angled triangle when both are known.

le. Square the length of each of the sides making the right angle, add squares together and take the square root of their sum. Thus (Fig. 26), length of $ac = 3$, and of $bc = 4$; then

$$ab = \sqrt{3^2 + 4^2} = \sqrt{9 + 16} = \sqrt{25}$$

$$\sqrt{25} = 5, \quad \text{or} \quad ab = 5$$

find the length of the base or altitude of a right-angled triangle when length of the hypothenuse and one side is known.

le. From the square of the length of the hypothenuse subtract the square the length of the other side and take the square root of the remainder.

find the area of a trapezium (Fig. 27).

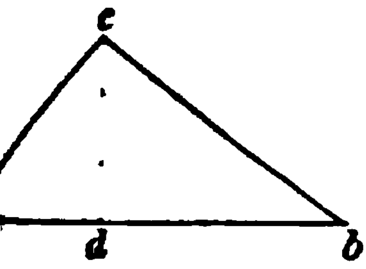

Fig. 25.
Scalene Triangle

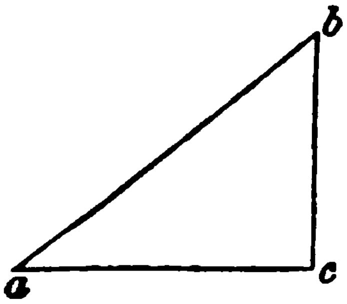

Fig. 26.
Right-angled Triangle

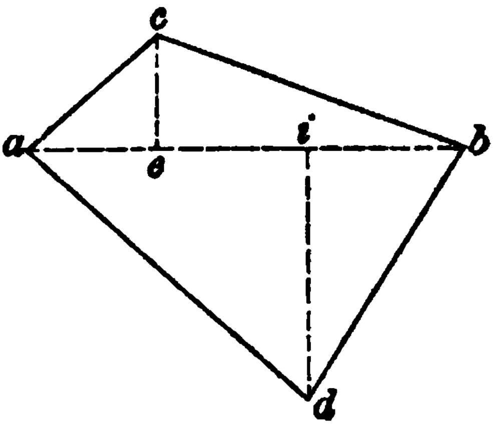

Fig. 27.
Trapezium

le. Multiply the diagonal by the sum of the two perpendiculars falling on it from the opposite angles and divide the product by 2. Thus,

$$\frac{ab \times (ce + di)}{2} = \text{area}$$

find the area of a trapezoid (Fig. 28).

le. Multiply the sum of the two parallel sides by the perpendicular distance between them and divide the product by 2.

compute the area of an irregular polygon.

le. Divide the polygon into triangles by means of diagonal lines and then together the areas of all the triangles, as A, B and C (Fig. 29).

To find the area of a regular polygon.

Rule. Multiply the length of a side by the perpendicular distance
center (as *ao*, Fig. 30), multiply that product by the number of sides and
the result by 2.

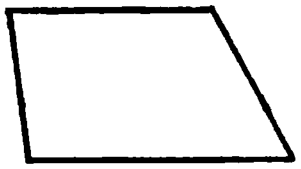

Fig. 28. Trapezoid

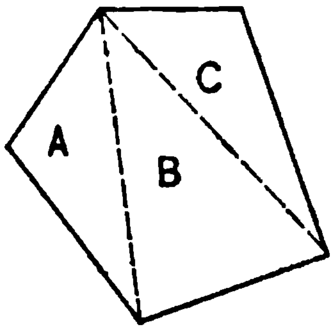

Fig. 29. Irregular Polygon

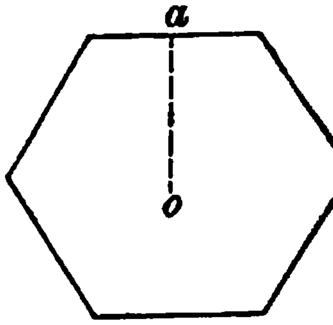

Fig. 30. Regular Poly

**To compute the area of a regular polygon when the length, only, of
is given.**

Rule. Multiply the square of the side by the multiplier opposite the na
the polygon in column *A* of the following table:

Table of Factors for Determining the Elements of Polygons

Name of polygon	Number of sides	*A* Factor for area	*B* Factor for radius of circum-scribing circle	*C* Factor for length of the sides	*L* Facto radiu inscr cir
Triangle...........	3	0.433013	0.5773	1.732	0.2
Tetragon...........	4	1	0.7071	1.4142	0.5
Pentagon...........	5	1.720477	0.8506	1.1756	0.6
Hexagon...........	6	2.598076	1	1	0 8
Heptagon..........	7	3.633912	1.1524	0.8677	1.0
Octagon............	8	4.828427	1.3066	0.7653	1.2
Nonagon...........	9	6.181824	1.4619	0.684	1.3
Decagon...........	10	7.694209	1.618	0.618	1.5
Undecagon.........	11	9.36564	1.7747	0.5634	1.7
Dodecagon.........	12	11.196152	1.9319	0.5176	1.8

**To compute the radius of a circle circumscribed about a regular polygon
the length, only, of a side is given.**

Rule. Multiply the length of a side of the polygon by the number in c
B of table.

Example. What is the radius of a circle that will contain a hexago
length of one side being 5 in?

Solution. $5 \times 1 = 5$ in.

**To compute the length of a side of a regular polygon inscribed in a
circle, when the radius of the circle is given.**

Rule. Multiply the radius of the circle by the number opposite the na
the polygon in column *C* of table.

Example. What is the length of the side of a pentagon contained in a
8 ft in diameter?

Solution. 8 ft diameter $\div 2 = 4$ ft radius; $4 \times 1.1756 = 4.7024$ ft.

To compute the length of a side of a regular polygon, when the radius of the inscribed circle is given.

Rule. Divide the radius of the inscribed circle by the number opposite the name of the polygon in column *D* of table.

To compute the radius of a circle that can be inscribed in a given regular polygon, when the length of a side is given.

Rule. Multiply the length of a side of the polygon by the number opposite the name of the polygon in column *D*.

Example. What is the radius of the circle that can be inscribed in an octagon, the length of one side being 6 in?

Solution. $6 \times 1.2071 = 7.2426$ in.

Circles

To compute the circumference of a circle.

Rule. Multiply the diameter by 3.1416. For many purposes, the multiplier $3\frac{1}{7}$ gives sufficiently accurate results.

Example. What is the circumference of a circle 7 in in diameter?

Solution. $7 \times 3.1416 = 21.9912$ in, or $7 \times 3\frac{1}{7} = 22$ in, the error in this last result being 0.0088 in.

To find the diameter of a circle when the circumference is given.

Rule. Divide the circumference by 3.1416, or for a very close approximate result, multiply by 7 and divide by 22.

To find the radius of an arc when the chord and rise or versed sine are given.

Rule. Square ONE-HALF the CHORD and the RISE; divide the sum of these squares by twice the rise; the result will be the radius.

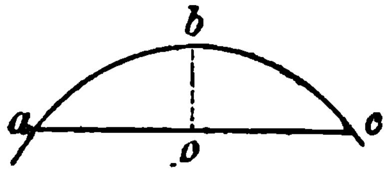

Fig. 31. Circular Arc, Chord and Rise

Example. The length of the chord *ac*, Fig. 31, is 48 in and the rise, *bo*, is 6 in. What is the radius of the arc?

Solution. Radius $= \dfrac{oc^2 + bo^2}{2\,bo} = \dfrac{24^2 + 6^2}{12} = 51$ in

To find the rise or versed sine of a circular arc, when the chord and radius are given.

Rule. Square the radius; also square one-half the chord; subtract the latter from the former and take the square root of the remainder. Subtract the result from the radius and the remainder will be the rise.

Example. A given arc has a radius of 51 in and a chord of 48 in. What is the rise?

Solution. Rise $=$ radius $- \sqrt{\text{radius}^2 - \frac{1}{2}\text{chord}^2} = 51 - \sqrt{2\,601 - 576} = 51 - 45$
$= 6$ in $=$ rise

To compute the area of a circle.

Rule. Multiply the square of the diameter by 0.7854, or multiply the square of the radius by 3.1416.

Example. What is the area of a circle 10 in in diameter?

Solution. $10 \times 10 \times 0.7854 = 78.54$ sq in, or $5 \times 5 \times 3.1416 = 78.54$ sq in.

Tables of Areas and Circumferences of Circles

The following tables will be found very convenient for finding the circumferences and areas of circles.

Areas and Circumferences of Circles

For diameters from 1/10 to 100, advancing by tenths

Dia.	Area	Circum.	Dia.	Area	Circum.	Dia.	Area	Circu
0.0			5.0	19.6350	15.7080	10.0	78.5398	31.41

Circular Arcs

To find, by the following table, the length of a circular arc when its height, or versed sine is given.

Rule. Divide the height by the chord; find in the column of h number equal to this quotient; take out the corresponding number column of lengths; and multiply this number by the given chord.

Example. The chord of an arc is 80 and its versed sine is 30. W length of the arc?

Solution. $30 \div 80 = 0.375$. The length of an arc for a height of from table, 1.34063. $80 \times 1.34063 = 107.2504 =$ length of arc.

Table of Lengths of Circular Arcs whose Radius is 1

Rule. Knowing the measure of the circle and the measure of the arc in minutes and seconds; take from the table the lengths opposite the nu degrees, minutes and seconds in the arc, and multiply their sum by the the circle.

Example. What is the length of an arc subtending an angle of 13 with a radius of 8 ft.

Solution. Length for 13° = 0.2268928
27′ = 0.0078540
8″ = 0.0000388
13° 27′ 8″ = 0.2347856
8
Length of arc = 1.8782848 ft

Lengths of Circular Arcs. Radius = 1

Length	Min	Length.	Deg	Length	Deg	Length

To compute the chord of an arc when the chord of half the arc and the sine are given.

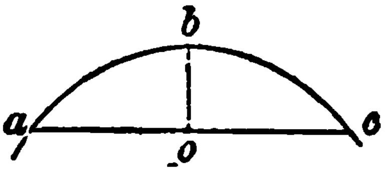

Fig. 32. Circular Arc, Chord and Rise

(The versed sine is the perpendicular *bo*, Fig.

Rule. From the square of the chord of half t subtract the square of the versed sine, and take the square root of the remainder.

Example. The chord of half the arc is 60, a versed sine 36. What is the length of the chord arc?

Solution. $60^2 - 36^2 = 2\,304$; $\sqrt{2\,304} = 48$; and $48 \times 2 = 96$, the chor

To compute the chord of an arc when the diameter and versed sine are gi

Multiply the versed sine by 2 and subtract the product from the dia then subtract the square of the remainder from the square of the diamet take the square root of that remainder.

Example. The diameter of a circle is 100 and the versed sine of an What is the chord of the arc?

Solution. $36 \times 2 = 72$; $100 - 72 = 28$; $100^2 - 28^2 = 9\,216$; $\sqrt{9\,21}$ the chord of the arc.

To compute the chord of half an arc when the chord of the arc and the sine are given.

Rule. Take the square root of the sum of the squares of the versed si of half the chord of the arc.

Example. The chord of an arc is 96 and the versed sine 36. What is the of half the arc?

Solution. $\sqrt{36^2 + 48^2} = 60$.

To compute the chord of half an arc when the diameter and versed si given.

Rule. Multiply the diameter by the versed sine and take the squa of their product.

To compute a diameter.

Rule 1. Divide the square of the chord of half the arc by the versed si

Rule 2. Add the square of half the chord of the arc to the square versed sine and divide this sum by the versed sine.

Example. What is the radius of an arc whose chord is 96 and whose sine is 36?

Solution. $48^2 + 36^2 = 3\,600$; $3\,600 \div 36 = 100$, the diameter; and the $= 50$.

To compute the versed sine.

Rule. Divide the square of the chord of half the arc by the diameter.

To compute the versed sine when the chord of the arc and the diamet given.

Rule. From the square of the diameter subtract the square of the and extract the square root of the remainder; subtract this root from the eter and halve the remainder.

To compute the length of an arc of a circle when the number of degree the radius are given.

Rule 1. Multiply the number of degrees in the arc by 3.1416 multipli the radius and divide by 180. The result will be the length of the arc same unit as the radius.

2. Multiply the radius of the circle by 0.01745 and the product by the in the arc.

ple. The number of degrees in an arc is 60 and the radius is 10 in. the length of the arc in inches?

tion. $10 \times 3.1416 \times 60 = 1884.96$; and $1884.96 \div 180 = 10.47$ in. Or, $0.01745 \times 60 = 10.47$ in.

compute the length of the arc of a circle when the length is given in de-, minutes and seconds.

le. (1) Multiply the number of degrees by 0.01745329 and the product radius. (2) Multiply the number of minutes by 0.00029 and that prod- by the radius. (3) Multiply the number of seconds by 0.0000048 times radius. (4) Add together these three results for the length of the arc. also, table, page 57.)

mple. What is the length of an arc of 60° 10′ 5″, the radius being 4 ft?

tion.
(1) $60° \times 0.01745329 \times 4 = 4.188789$ ft
(2) $10' \times 0.00029 \times 4 = 0.0116$ ft
(3) $5'' \times 0.0000048 \times 4 = 0.000096$ ft
(4) The length of the arc $= 4.200485$ ft

compute the area of a sector of a circle when the degrees of the arc and radius are given (Fig. 33).

The degrees of the arc are the same as the angle *aob*.)

le. Multiply the number of degrees in the arc by area of the whole circle and divide by 360.

mple. What is the area of a sector of a circle whose is 5 and length of arc 60°?

tion. Area of circle $= 10 \times 10 \times 0.7854 = 78.54$

, area of sector $= \dfrac{78.5 \times 60}{360} = 13.09$

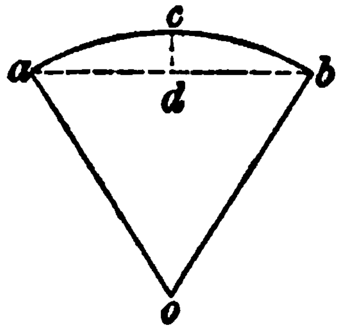

Fig. 33. Sector of Circle

te. If the length of the arc is given in degrees and tes, reduce it to minutes, multiply by the area of the whole circle and divide 600.

compute the area of a sector of a circle when the length of the arc and s are given.

le. Multiply the length of the arc by half the length of the radius. The act is the area.

compute the area of a segment of a circle when the chord and versed sine arc and the radius or diameter of the circle are given.

he versed sine is the distance *cd*, Fig. 33.)

le 1. **When the segment is less than a semicircle.** (1) Find the area of ector having the same arc as the segment. (2) Find the area of a triangle d by the chord of the segment and the radii of the sector. (3) Take the ence of these areas.

le 2. **When the segment is greater than a semicircle.** Find, by the pre- g rule, the area of the lesser portion of the circle and subtract it from the f the whole circle. The remainder will be the area.

compute the area of the surface of a sphere.

e. Multiply the diameter by the circumference. The product will be ea of the surface.

Example. What is the area of the surface of a sphere 10 in in diam

Solution. Circumference of sphere = $10 \times 3.1416 = 31.416$ in; 10
= 314.16 sq in, the area of surface of sphere.

To compute the total area of the surface of a segment of a sphere.

Rule. Multiply the height (*bc*, Fig. 34) by the circumference of th and add the product to the area of the base.

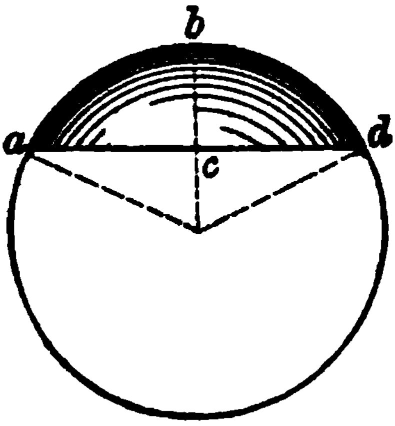

Fig. 34.
Segment of Sphere

To find the area of the base, having the diameter of the sphere and the length of the versed sine of the arc *abd*, find the length of the chord *ad* by the rule on page 58. Having, then, the length of the chord *ad* for the diameter of the base, find the area of the base.

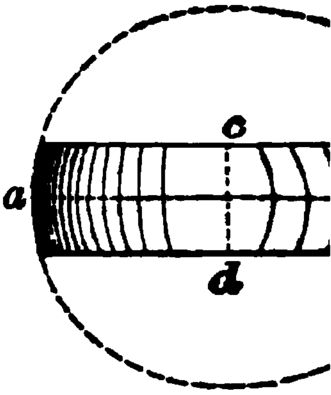

Fig. 35.
Zone of Sphe

Example. The height, *bc*, of a segment *abd*, is 36 in, and the diamete sphere is 100 in (Fig. 34). What is the area of the convex surface and t of the whole surface?

Solution. $100 \times 3.1416 = 314.16$ in, the circumference of sphere
$36 \times 314.16 = 11309.76$ sq in, the area of the convex surfac
$100 - (36 \times 2) = 28$
$\sqrt{100^2 - 28^2} = 96$, the chord *ad*
$96^2 \times 0.7854 = 7238.2464$ sq in, the area of the base
$11309.76 + 7238.2464 = 18548.0064$ sq in, the total area

To compute the total area of the surface of a spherical zone.

Rule. Multiply the height, *cd* (Fig. 35), by the circumference of the for the convex surface and add to it the area of the two ends for the total a

Spheroids, or Ellipsoids of Revolution

Definition. Spheroids, or ellipsoids, are figures generated by the rev of a semiellipse about one of its diameters.

When the revolution is about the long diameter, they are PROLATE when it is about the short diameter, they are OBLATE.

A PROLATE SPHEROID is approximately cigar-shaped and an OBLATE SP is, in form, somewhat like a watch.

To compute the area of the surface of a spheroid.

Let $a = \frac{1}{2}$ the long axis; let $b = \frac{1}{2}$ the short axis;

let
$$\frac{a^2 - b^2}{a^2} = e^2 \quad \text{or} \quad e = \sqrt{\frac{a^2 - b^2}{a^2}}$$

Then, the area of the SURFACE OF THE OBLATE SPHEROID

$$= 2\pi a^2 + \frac{\pi b^2}{e} \log\left(\frac{1 + e}{1 - e}\right)$$

and the area of the SURFACE OF THE PROLATE SPHEROID

$$= 2\pi b^2 + 2\pi ab \frac{\sin^{-1} e}{e}$$

the first formula, NATURAL LOGARITHMS must be used. The natural loga- may be obtained by multiplying the common logarithm by 2.302. The of the expression $\sin^{-1} e$ may be determined by finding the angle whose sine is equal to e and dividing this angle by

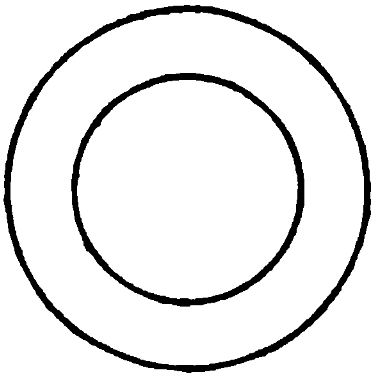

Fig. 36. Circular Ring

Although the above formulas are compli- no simpler rules that give correct results can be

compute the area of the surface of a cylinder.

Multiply the length of the cylinder by the ference of one of the ends and add to the the areas of the two ends.

compute the area of a circular ring (Fig. 36).

Find the area of both circles and subtract the area of the smaller from of the larger; the remainder will be the area of the ring.

compute the area of the surface of a cone.

Multiply the circumference of the base by one-half the slant-height of the cone, for the convex area. Add to this the area of the base, for whole area.

Example. The diameter of the base of a cone is 3 in and the slant-height 15 in. is the area of the surface of the cone?

Solution.	3×3.1416	= 9.4248	= circumference of base
	$9.4248 \times 7\frac{1}{2}$	= 70.686 sq in	= area of convex surface
	$3 \times 3 \times 0.7854$	= 7.068 sq in	= area of base
Area of entire surface of cone		= 77.754 sq in	

compute the area of the surface of the frustum of a cone (Fig. 37).

37. Frustum of Cone

Rule. Multiply the sum of the circumferences of the two ends by the slant-height of the frustum and divide by 2, for the area of the convex surface. Add the areas of the two ends.

To compute the area of the surface of a pyramid.

Rule. Multiply the perimeter of the base by one-half the slant-height and add to the product the area of the base.

To compute the area of the surface of the frustum of a pyramid.

Rule. Multiply the sum of the perimeters of the two ends by the slant-height of the frustum, halve the product, and add to the result the areas of the two ends.

Mensuration of Solids

compute the volume of a prism. (See page 38 for definition of a prism.)

Multiply the area of the base or end by the altitude or perpendicular

This rule applies to prisms with bases or ends of any shape, as long as these or ends are parallel.

To compute the volume of a prismoid.

Definition. A prismoid is a solid with parallel but unequal ends o and with quadrilateral sides.

Rule. To the sum of the areas of the two ends or bases add four ti area of the middle section parallel to them, and multiply this sum by o of the altitude or perpendicular height.

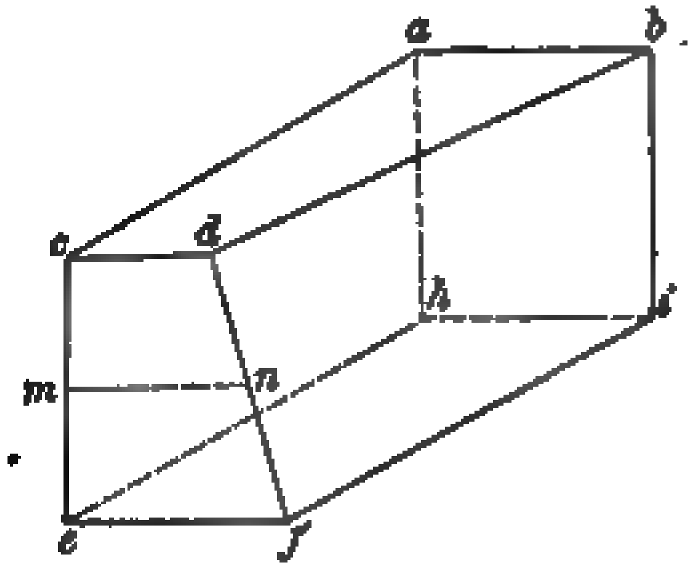

Fig. 38. Quadrangular Prismoid

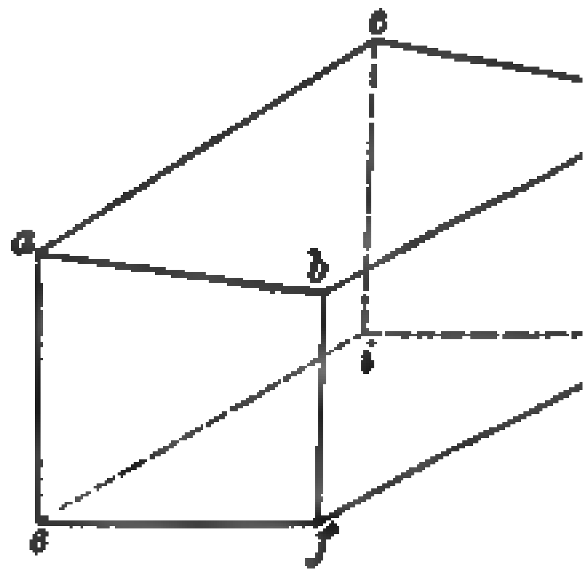

Fig. 39. Prism Truncated Obliq

Example. What is the volume of a quadrangular prismoid, as Fig. which $ab = 6$ in, $cd = 4$ in, $ac = he = 10$ in, $ce = 8$ in, $ef = 8$ in and $ih = 6$

Solution. Area of top $= \frac{6+4}{2} \times 10 = 50$ sq in

Area of bottom $= \frac{8+6}{2} \times 10 = 70$ sq in

Area of middle section $= \frac{6+6}{2} \times 10 = 60$ sq in

$[50 + 70 + (4 \times 60)] \times \frac{4}{3} = 480$ cu in

b

Note. The length of the end (middle section (as at mn, in Fig. $\frac{cd + ef}{2}$

To find the volume of a prism tru obliquely.

Rule. Multiply the area of the b the average height of the edges.

Example. What is the volume truncated prism (Fig. 39) in which in, $fh = 10$ in, $ea = 10$ in, $ci = 12$ in, di in and $fb = 8$ in?

Fig. 40. Wedge or Right Triangular Prism

Solution. Area of base $= 6 \times 10$ sq in

Average height of edges $= \frac{10 + 12 + 8 + 10}{4} = 10$ in

$60 \times 10 = 600$ cu in

compute the volume of a wedge or right triangular prism when the ends are ...lel and equal.

...le. Multiply the area of one end by the length of the wedge.

compute the volume of a wedge when the ends are not parallel.

...le. Add together the lengths of the three edges, *ab*, *cd* and *ef* (Fig. 40); ...iply their sum by the altitude or perpendicular height of the wedge, and ...ly the breadth of the back, and divide the product by 6.

Regular Polyhedrons

...inition. A regular polyhedron is a solid contained within a certain num... ...similar and equal plane faces, all of which are equal regular polygons. ...following is a list of all the regular polyhedrons:

...) The TETRAHEDRON, or pyramid.
...) The HEXAHEDRON, or cube, which has six square faces.
...) The OCTAHEDRON, which has eight triangular faces.
...) The DODECAHEDRON, which has twelve pentagonal faces.
...) The ICOSAHEDRON, which has twenty triangular faces.

compute the volume of a regular polyhedron.

...le 1. **When the radius of the circumscribing sphere is given.** Multiply ...cube of the radius of the sphere by the multiplier opposite to the polyhedron ...lumn 2 of the following table.

...le 2. **When the radius of the inscribed sphere is given.** Multiply the cube ...e radius of the inscribed sphere by the multiplier opposite to the polyhedron ...lumn 3 of the table.

...le 3. **When the area of the surface of the polyhedron is given.** Cube the ...ce given, extract the square root, and multiply the root by the multiplier ...site to the polyhedron in column 4 of the table.

...ble of Factors for Determining the Volumes of Regular Polyhedrons

Figure	1 Number of sides	2 Factor for volume by radius of circumscribing sphere	3 Factor for volume by radius of inscribed circle	4 Factor for volume by surface
...rahedron........	4	0.5132	13.85641	0.0517

compute the volume of a cylinder.

...le. Multiply the area of the base by the altitude or length.

compute the volume of a cone.

...le. Multiply the area of the base by one-third the altitude.

compute the volume of the frustum of a cone (Fig. 41).

...le. Add together the squares of the diameters of the two ends or bases ...the product of the two diameters; multiply this sum by 0.7854, and this ...uct by the altitude, and then divide this last product by 3.

Example. What is the volume of a frustum of a cone 9 in in height, diameter at the base and 3 in in diameter at the top?

Solution. $5^2 + 3^2 = 34$. $3 \times 5 = 15$. $15 + 3$ the sum of the squares of the two diameters ad the product of the diameters of the ends. $49 \times$ $= 38.4846$.

$$\frac{38.4846 \times 9}{3} = 115.4538 \text{ cu in}$$

To compute the volume of a pyramid.

Rule. Multiply the area of the base by the a or perpendicular height, and take one-third product.

To compute the volume of the frustum of a pyra

Rule. Find the height that the pyramid woul the top were put on, and then compute the vol the completed pyramid and the volume of th added; subtract the latter from the former, and the remainder will be the of the frustum.

Fig. 41. Frustum of Cone

To compute the volume of a sphere.

Rule. Multiply the cube of the diameter by 0.5236.

To compute the volume of a segment of a sphere.

Rule 1. To three times the square of the radius of its base add the sq its height; multiply this sum by the height and the product by 0.5236.

Rule 2. From three times the diameter of the sphere subtract twice the height of the segment; multiply this remainder by the square of the height and the product by 0.5236.

Example. The segment of a sphere has a radius, *ac* (Fig 42), of 7 in for its base, and a height, *cb*, of 4 in: what is its volume?

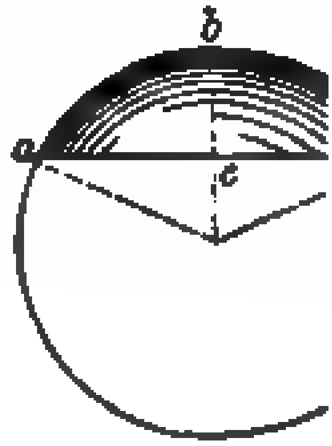

Fig. 42. Segment of

Solution. (By Rule 1) $3 \times 7^2 = 147$, and $147 + 4^2 = 163$, or three times the square of the radius of the base plus the square of the height. $163 \times 4 \times 0.5236 = 341.3872$ cu in = the volume c segment.

Second Solution. By the rule for findi diameter of a circle when a chord and its sine are given, we find that the diameter sphere in this case is 16.25 in, then, by F $(3 \times 16.25) - (2 \times 4) = 40.75$; and $40.75 \times$ $0.5236 = 341.3872$ cu in, the volume c segment.

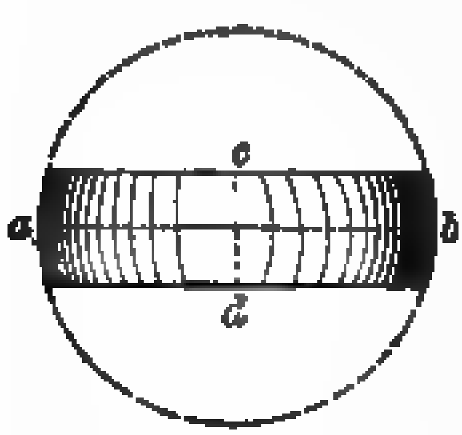

Fig. 43. Zone of Sphere

To compute the volume of a spherical zone.

Definition. The part of a sphere includ tween two parallel planes (Fig. 43).

Rule. To the sum of the squares of the radii of the two ends add one of the square of the height of the zone; multiply this sum by the height an product by 1.5708.

...mpute the volume of a prolate spheroid. (See page 60.)

...le. Multiply the square of the short axis by the long axis and this product ...5236.

...mpute the volume of an oblate spheroid.

...le. Multiply the square of the long axis by the short axis and this product ...5236.

...mpute the volume of a paraboloid of revolution (Fig. 44).

...le. Multiply the area of the base ... the altitude.

...mpute the volume of a hyperbo- ...revolution (Fig. 45).

...le. To the square of the radius ...e base add the square of the ...e diameter; multiply this sum ...e height and the product by ....

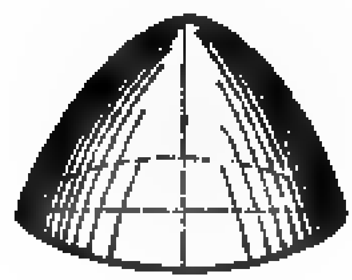

Fig. 44. Paraboloid of Revolution Fig. 45. Hyperboloid of Revolution

...mpute the volume of any figure ...olution.

...le. Multiply the area of the generating surface by the circumference ...ibed by its center of gravity.

...mpute the volume of an excavation, where the ground is irregular and ...ttom of the excavation is level (Fig. 46).

...le. Divide the surface of the ground to be excavated unto equal squares ...out 10 ft on a side, and ascertain by means of a level the height of each ...er, a, a, a, b, b, b, etc., above the level to which the ground is to be excavated. ...n add together the heights of all the corners that come in one square only. Next take twice the sum of the heights of all the corners that come in two squares, as b, b, b; next three times the sum of the heights of all the corners that come in three squares, as c, c, c; and then four times the sum of the heights of all the corners that belong to four squares, as d, d, d, etc. Add together all these quantities, and multiply their sum by one-fourth the area of one of the squares. The result will be the volume of the excavation.

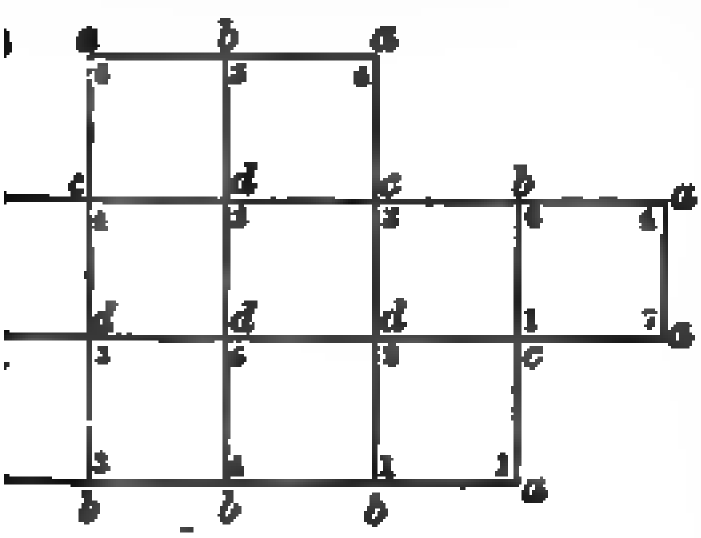

Fig. 46. Plan of Excavation

...mple. Let the plan of an excavation for a cellar be as shown in Fig. 46, ...the heights of each corner above the proposed bottom of the cellar be as ...n by the numbers in the figure. Then the volume of the cellar will be as ...ws, the area of each square being $10 \times 10 = 100$ sq ft:

...lume $= \frac{1}{4}$ of $100\ (a\text{'s} + 2\,b\text{'s} + 3\,c\text{'s} + 4\,d\text{'s})$

The a's in this case	$= 4 + 6 + 3 + 2 + 1 + 7 + 4$	$= 27$
$2 \times$ the sum of the b's	$= 2 \times (3 + 6 + 1 + 4 + 3 + 4)$	$= 42$
$3 \times$ the sum of the c's	$= 3 \times (1 + 3 + 4)$	$= 24$
$4 \times$ the sum of the d's	$= 4 \times (2 + 3 + 6 + 2)$	$= 52$
		145

...lume $= 25 \times 145 = 3\,625$ cu ft, the quantity of earth to be excavated.

4. GEOMETRICAL PROBLEMS

Problem 1. To bisect, or divide into equal parts, a given line, ab (Fig

From *a* and *b*, with any radius greater than half of *ab*, describe ar secting in *c* and *d*. The line *cd*, connecting these intersections, will b and be perpendicular to it.

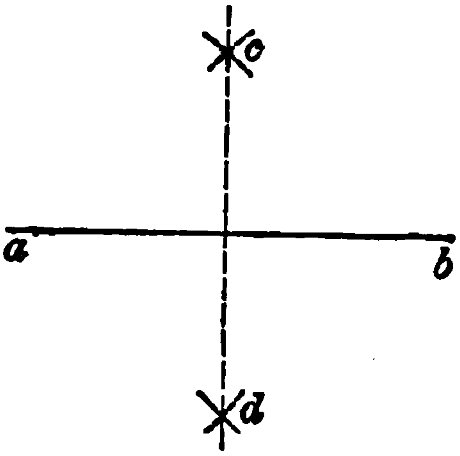

Fig. 47. Line Bisected

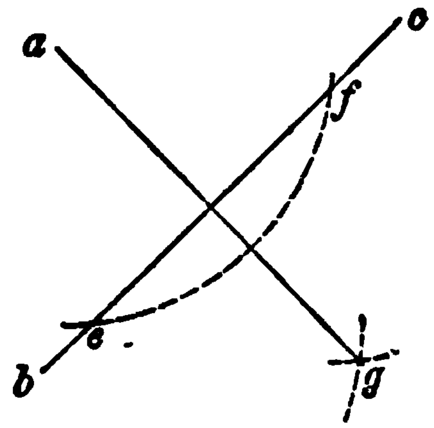

Fig. 48. Perpendicular from Point to Given Line

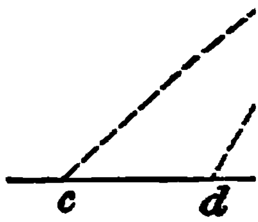

Fig. 49. Perpe from Point to Gi

Problem 2. To draw a perpendicular to a given straight line from a poi out it.

First Method (Fig. 48). From the point *a* describe an arc cutting *bc* in two places, as *e* and *f*. From *e* and *f* describe two arcs, with th radius, intersecting in *g*; then a line drawn from *a* to *g* is perpendicular line *bc*.

Second Method (Fig. 49). From any two points, *d* and *c*, at some d apart in the given line, and with radii *da* and *ca* respectively, descr

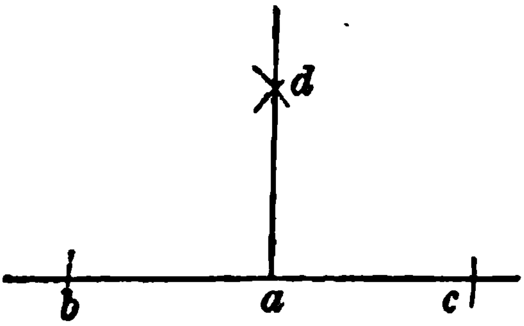

Fig. 50. Perpendicular from Point in Given Line

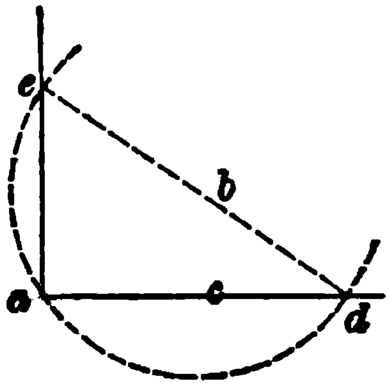

Fig. 51. Perpendicular from Extremity of Given Line

cutting at *a* and *e*. Draw *ae*, which is the perpendicular reequired. method is useful where the given point is opposite the end of the line, or so.

Problem 3. To draw a perpendicular to a straight line from a given p in that line.

First Method (Fig. 50). With any radius, from the given point *a* in th describe arcs cutting the line in the points *b* and *c*. Then with *b* and *c* as c and with any radius greater than *ab* or *ac*, describe arcs cutting each o *d*. The line *da* is the perpendicular required.

...nd Method (Fig. 51), when the given point is at the end of the line. ...e any point, *b*, outside of the line, and with a radius *ba*, describe a semi... passing through *a* and cutting the given line ... Through *b* and *d* draw a straight line inter...ing the semicircle at *e*. The line *ea* will then be ...ndicular to the line *ac* at the point *a*.

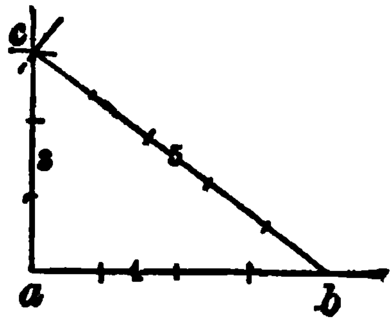

Fig. 52. Perpendicular from Extremity of Given Line

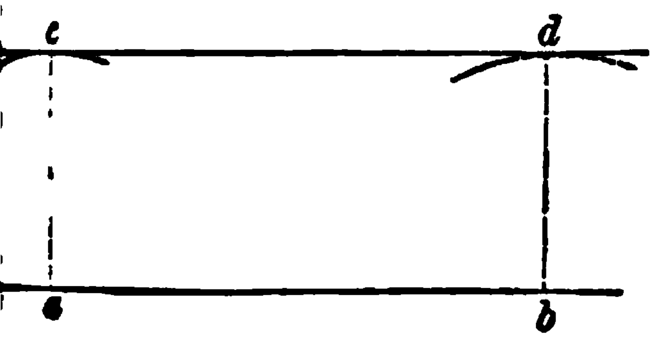
...ird Method (Fig. 52), or the 3, 4 and 5 Method. ...n the point *a* on the given line measure off 4 in, ...ft, or 4 of any other unit and with the same unit ...easure describe an arc, with *a* as a center and ...its as a radius. Then from *b* describe an arc ...a radius of 5 units, cutting the first arc in *c*. ...ne *ca* is the perpendicular required. This method ...rticularly useful in laying out a right angle on ...ground, or framing a house where the foot is used as the unit and the lines ...laid off by the straight-edge.

...laying out a right angle on the ground, the proportions of the triangle may ...30, 40 and 50, or any other multiple of 3, 4 and 5; and it can best be laid ...with the tape. Thus, first measure off, say 40 feet from *a* (Fig. 52) on the ...n line; then let one person hold the end of the tape at *b*, another hold the tape at the 80-ft mark at *a*, and a third person take hold of the tape at the 50-ft mark, with his thumb and finger, and pull the tape taut. The 50-ft mark will then be at the point *c* in the line of the perpendicular.



...g. 53. Straight Line Parallel to Given Line

Problem 4. To draw a straight line parallel to a given line at a given distance away (Fig. 53).

...m any two points near the ends of the given line describe two arcs about ...site the given line. Draw the line *cd* tangent to these arcs and it will be ...llel to *ab*.

...blem 5. To construct an angle equal to a given angle (Fig. 54).

...th the point *A*, at the apex of the given angle, as a center, and any radius, ...ibe the arc *BC*. With the point *a*, at the vertex of the new angle, as a

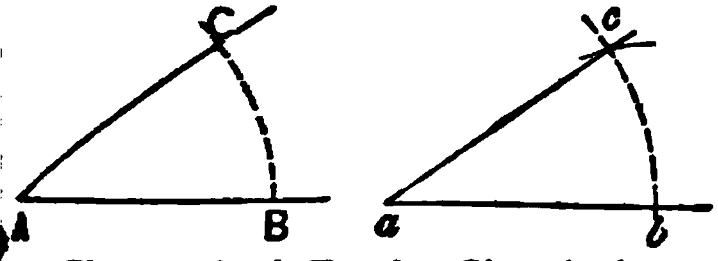


Fig. 54. Angle Equal to Given Angle

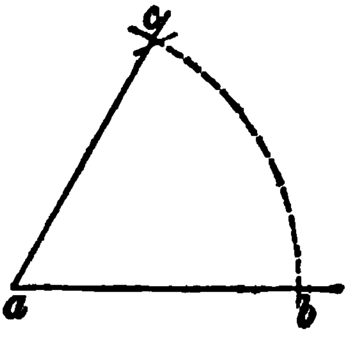

Fig. 55. Angle of 60°

...r, and with the same radius as before, describe an arc, as *BC*. With *BC* ...radius and *b* as a center, describe an arc cutting the other arc at *c*. Then ...cab be equal to the given angle *CAB*.

...blem 6. From a point on a given line to draw a line making an angle of ...th the given line (Fig. 55).

...e any distance, as *ab*, as a radius, and with *a* as a center, describe the arc. ...With *b* as a center and with the same radius, describe an arc cutting the

first one at c. Draw from a a line through c, and it will make with ab a
of 60°.

Problem 7. From a given point, A, on a given line, AE, to draw a line an angle 45° with the given line (Fig. 56).

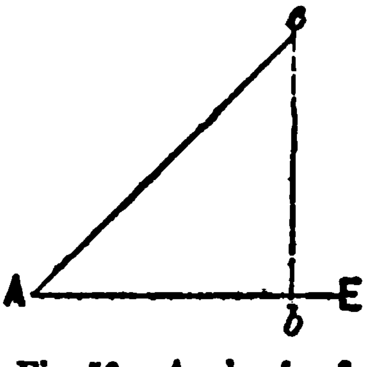

Fig. 56. Angle of 45°

Measure off from A, on AE, any distance, at b draw a line perpendicular to AE. Meas on this perpendicular bc equal to Ab and draw from A through c. This line Ac will make an a 45° with AE.

Problem 8. From any point, A, on a given draw a line which will make any desired angle given line (Fig. 57).

To solve this problem the tables of chords on p to 89 are used. Find in the table the length o to a radius 1, for the given angle. Then ta radius, as large as convenient and describe an arc of a circle bc, with center. Multiply the chord of the angle, found in the table, by the le the radius Ab, and with the product as a new radius and with b as a describe a short arc cutting bc in d. Draw a line from A through d and it will make the required angle with DE.

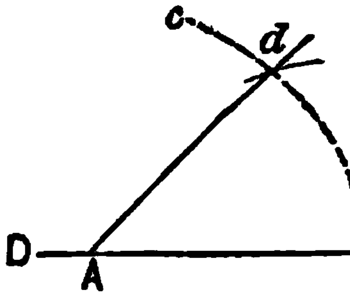

Fig. 57. Line Maki Angle with Given

Example. Draw a line from A on DE, making an angle of 44° 40′ with DE (Fig. 57).

Solution. The largest convenient radius for the arc is 8 in. With A as a center and 8 in as a radius, describe the arc bc. In the table of chords, the chord for an angle or arc of 44° 40′ to a radius 1 is 0.76. Multiplying this by 8 in, the length of the new radius is 6.08 in; and with this as radius and with center, describe an arc cutting bc in d. Ad will be the line required.

Problem 8a. To lay off a given angle approximately, by means of an two-foot rule.

Tables of Angles Corresponding to Openings of a Two-Foot Rule*

* Trautwine.

Lay one leg of the rule on the paper or board with its inner edge coinciding with the given line. Open the rule until the distance between the inner edges at ends correspond with that given for the angle in the following table; then draw a line by marking along the inner edge of the other leg, and it will give the desired angle within a very close approximation.

Problem 9. To bisect a given angle, as BAC (Fig. 58).

With *A* as a center and any radius, describe an arc, as *cb*. With *c* and *b* as centers, and any radius greater than one-half of *cb*, describe two arcs, intersecting at *d*. Draw from *A* a line through *d* and it will bisect the angle *BAC*.

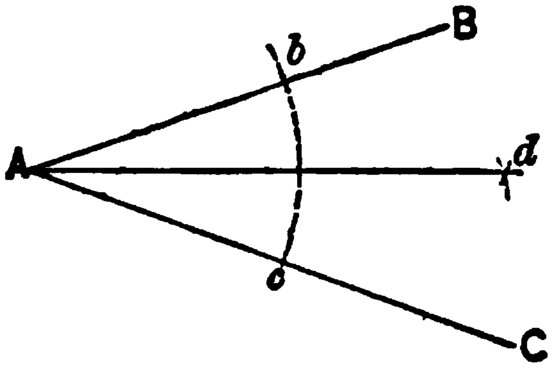

Fig. 58. Angle Bisected

Problem 10. To bisect the angle included between two lines, as AB and CD, when the vertex of the angle is not on the drawing (Fig. 59).

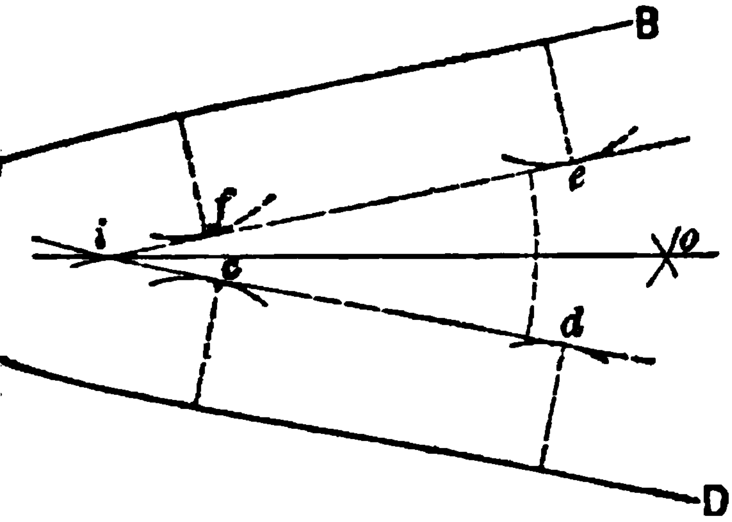

Fig. 59. Angle Bisected. Angle not on Drawing

Draw *fe* parallel to *AB* and *cd* parallel to *CD*, so that the two lines intersect, as at *i*. Bisect the angle *eid*, as in the preceding problem, and draw a line through *i* and *o* which will bisect the angle between the two given lines.

Problem 11. Through two given points, B and C, to describe an arc of a circle with a given radius (Fig. 60).

With *B* and *C* as centers and with a radius equal to the given radius, describe two arcs intersecting at *A*. With *A* as a center and the same radius, describe the arc *bc*, which will pass through the given points, *B* and *C*.

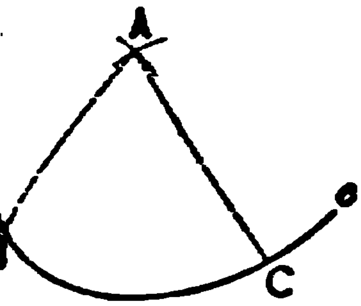

Fig. 60. Circular Arc Through Two Given Points

Problem 12. To find the center of a given circle (Fig. 61).

Draw any chord in the circle, as *ab*, and bisect this chord by the perpendicular *cd*. This line will pass through the center of the circle and *ef* will be a diameter of the circle. Bisect *ef*, and the center *o* will be the center of the circle.

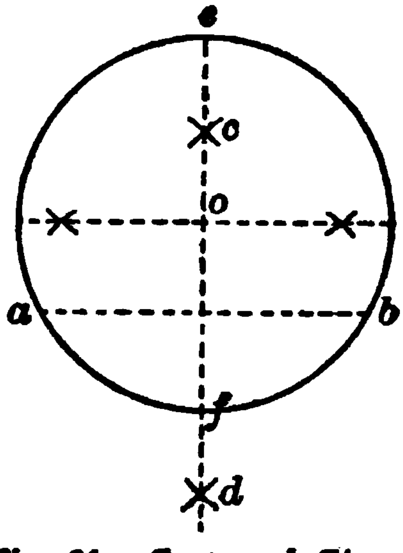

Fig. 61. Center of Given Circle

Problem 13. To draw a circular arc through three given points, as A, B and C (Fig. 62).

Draw lines from *A* to *B* and from *B* to *C*. Bisect *AB* and *BC* by the lines *aa* and *cc* and prolong these lines until they intersect at *o*, which will be the center for the arc sought. With *o* as a center and *Ao* as radius, describe the arc *ABC*.

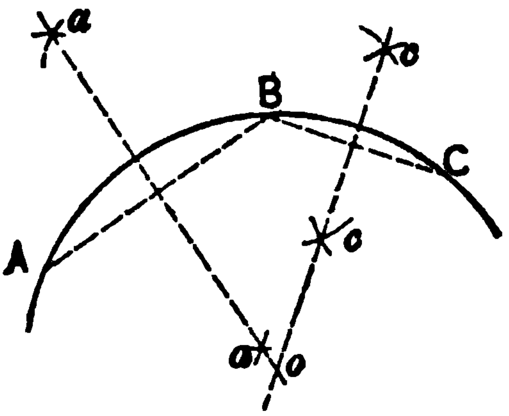

Fig. 62. Circular Arc Through Three Given Points

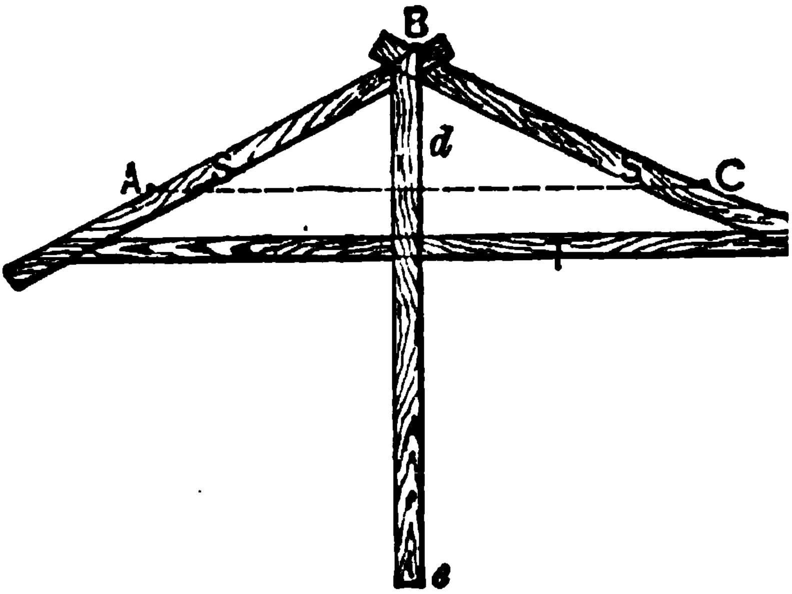

Fig. 63. Frame for Drawing Circular Ar

Problem 14. To describe a circular arc passing through three given when the center is not available, by means of a triangle (Fig. 63).

Let *A*, *B* and *C* be the given points. Insert two stiff pins or nails at *A* a Place two strips of wood, *SS*, as shown in the figure, one against *A*, the against *C*, and inclined so that their intersection shall come at the third *B*. Fasten the strips together at their intersection and nail a third stri to their other ends, so as to make a firm triangle. Place the pencil-point and, keeping the edges of the triangle against *A* and *C*, move the triangle t left and right. The pencil-point will describe the required arc.

When the points *A* and *C* are at the same distance from *B*, if a strip of is nailed to the triangle, so that its edge *de* is at right-angles to a line jo *A* and *C*, as the triangle is moved one way or the other, the edge *de* will al point to the center of the circle. This principle is used in linear perspecti

Problem 15. To describe a circular arc which will be tangent at a given A, to a straight line, and pass through a given point, C, outside the line (Fig

Draw from *A* a line perpendicular to the given line. Connect *A* and *C* straight line and bisect this line by the perpendicular *ac*. The point where two perpendiculars intersect is the center of the circle.

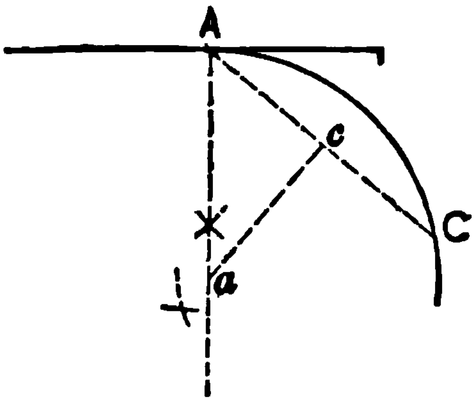

Fig. 64. Circular Arc Tangent to Line at Given Point

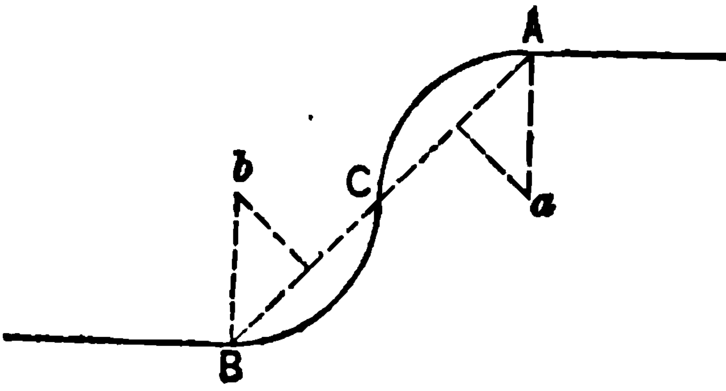

Fig. 65. Reversed Curve Between Parallel

Problem 16. To connect two parallel lines by a reversed curve compos two circular arcs of equal radius, and tangent to the lines at given points, and B (Fig. 65).

Join *A* and *B* and divide the line into two equal parts at *C*. Bisect *CA* *CB* by perpendiculars. At *A* and *B* erect perpendiculars to the given lines the intersections *a* and *b* will be the centers of the arcs composing the req curve.

[...]lem 17. On a given line, as AB (Fig. 66), to construct a compound curve [...]ree arcs of circles, the radii of the two side arcs being equal and of a given [...]h, and their centers [...]g in the given line. The [...]al arc is to pass through [...]en point, C, on the perpendicular bisecting the given [...], and is to be tangent to [...]other two arcs.

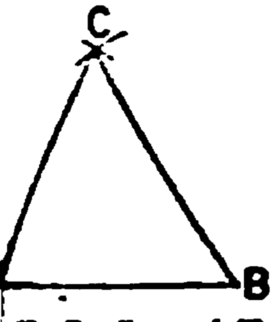
[...]raw the perpendicular [...]. Lay off Aa, Bb and Cc, [...]h equal to the given radius [...] the side arcs; draw ac; [...]ct ac by a perpendicular. [...]e intersection of this line [...]h the perpendicular CD [...]e required center of the [...]tral arc. Through a and b draw the lines Dc and De'; from a and b, with [...] given radius, equal to Aa, Bb, describe the arcs Ae' and Be; from D as a center, and with CD as a radius, describe the arc eCe' which completes the curve required.



[...]. 67. Equilateral Triangle on Given Base

Problem 18. To construct a triangle upon a given straight line or base, the length of the two sides being given (Figs. 67 and 68).

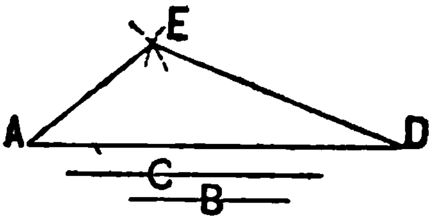


Fig. 68. Scalene Triangle on Given Base

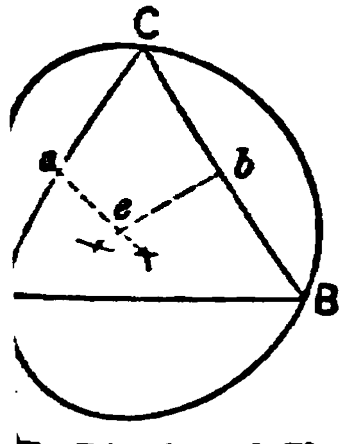
First. An equilateral triangle (Fig. 67). With the [...]mities A and B of the given line as centers and with AB as a radius. [...]ibe arcs cutting each other at C. Join AC and BC.

[...]cond. A scalene triangle (Fig. 68). Let AD be the given base and the other [...] sides be equal to C and B. With D as a center, and with a radius equal to C, describe at E an arc of indefinite length. With A as a center and with B as a radius, describe an arc cutting the first at E. Join E with A and D. ADE is the required triangle.



[...]. Triangle and Circumscribed Circle

Problem 19. To describe a circle about a triangle (Fig. 69).

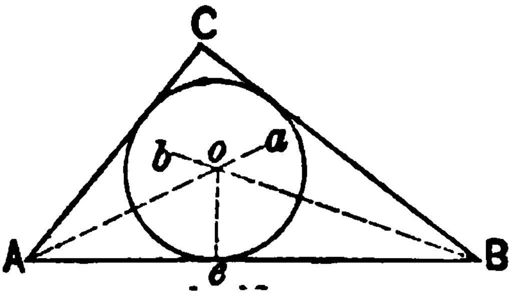


Fig. 70. Triangle and Inscribed Circle

Bisect two of the sides, as AC and CB, of the triangle, and at their centers, erect perpendicular lines, [...]d be, intersecting at e. With e as a center, and eC as a radius, describe [...]. It will pass through A and B.

[...]em 20. To inscribe a circle in a triangle (Fig. 70).

[...]t two of the angles, A and B, of the triangle by lines cutting each other [...] With o as a center, and with oe as a radius, describe a circle. It will be [...]t to the other two sides.

Problem 21. To inscribe a square in a circle and to describe a circle ab square (Fig. 71).

To inscribe the square. Draw two diameters, AB and CD, at right-a to each other. Join the points A, D, B and C. $ADBC$ is the inscribed sq

To describe the circle. Draw the diagonals as before, intersecting at E, with E as a center and AE as a radius, describe the circle.

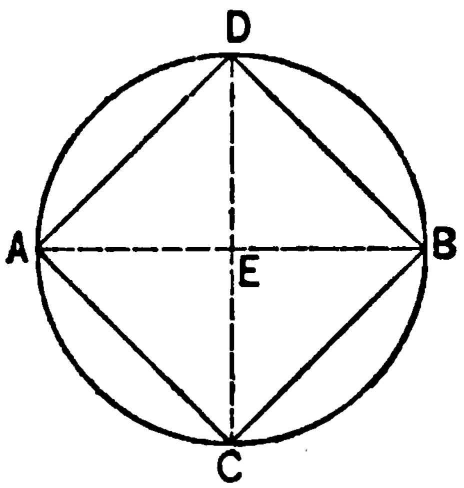

Fig. 71. Inscribed Square and Circumscribed Circle

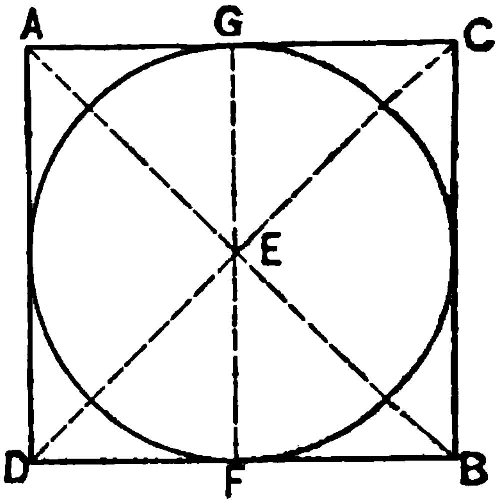

Fig. 72. Inscribed Circle and Circumscribed Square

Problem 22. To inscribe a circle in a square and to describe a square ab circle (Fig. 72).

To inscribe the circle. Draw the diagonals AB and CD, intersecting Draw the perpendicular EG to one of the sides. Then with E as a center EG as a radius, describe a circle. It will be tangent to all four sides o square.

To describe the square. Draw two diameters, AB and CD, at right- to each other, and prolonged beyond the circumference. Draw the dia GF, bisecting the angle CEA or BED. Draw lines through G and F pe dicular to GF, and terminating in the diagonals. Draw AD and CB to plete the square.

Problem 23. To inscribe a pentagon in a circle (Fig. 73).

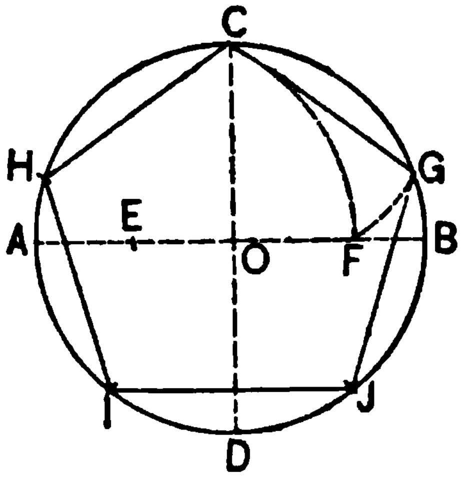

Fig. 73. Circle and Inscribed Pentagon

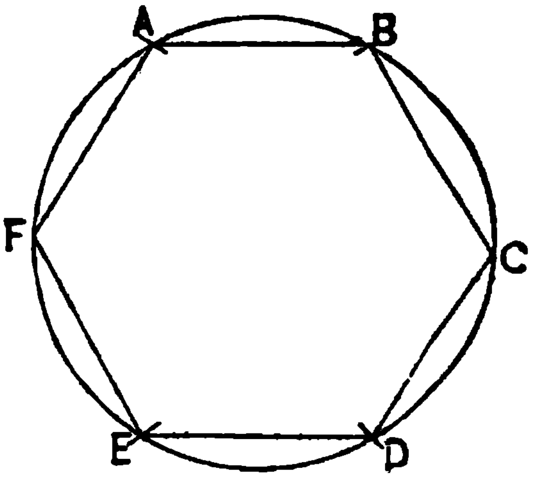

Fig. 74. Circle and Inscribed Hexagon

Draw two diameters, AB and CD, at right-angles to each other. Bisec at E. With E as a center and EC as a radius, cut OB at F. With C as a c and CF as a radius, cut the circle at G and H. With these points as center the same radius, cut the circle at I and J. Join I, J, G, C and H. $IJGC$ the inscribed regular pentagon.

Problem 24. To inscribe a regular hexagon in a circle (Fig. 74).

Lay off on the circumference the radius of the circle six times, and connect the points.

Problem 25. To construct a regular hexagon upon a given straight line, AB (Fig. 75).

From *A* and *B*, with a radius equal to *AB*, describe arcs intersecting at *O*. With *O* as a center and a radius equal to *AB*, describe a circle, and from *A* or *B* lay off the lengths *BC*, *CD*, *DE*, *EF* and *FA* on the circumference of the circle. *ABCDEFA* is the required regular hexagon.

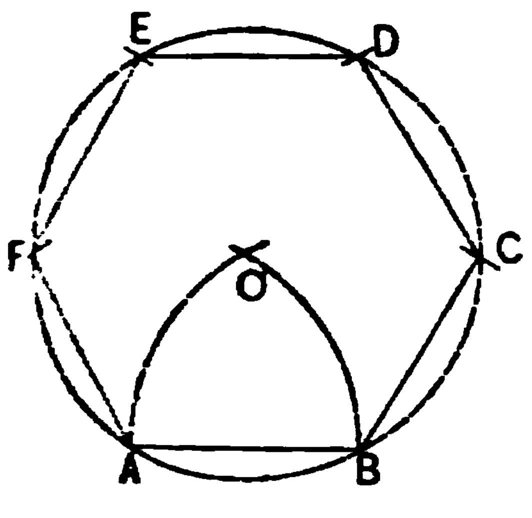

Fig. 75. Regular Hexagon on Given Line

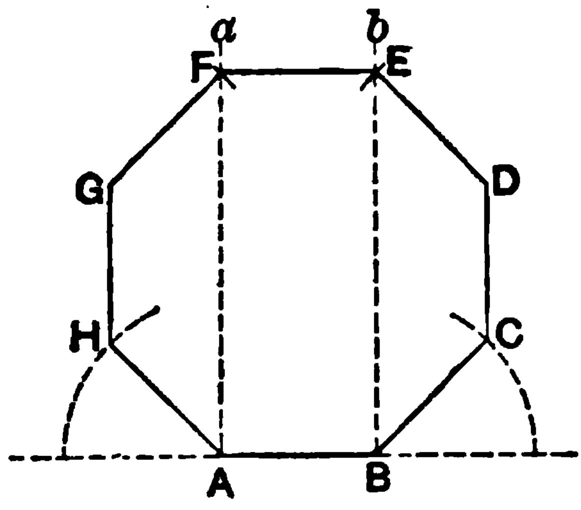

Fig. 76. Regular Octagon on Given Line

Problem 26. To construct a regular octagon upon a given straight line, AB (Fig. 76).

Produce the line *AB* both ways and draw the perpendiculars *Aa* and *Bb*, of indefinite length. Bisect the external angles at *A* and *B* and make the length of the bisecting lines equal to *AB*. From *H* and *C* draw lines parallel to *Aa* or *Bb* and equal in length to *AB*. From *G* and *D* as centers describe arcs, with radius *AB*, cutting the perpendiculars *Aa* and *Bb* in *F* and *E*. Draw *GF*, *FE* and *ED*. *ABCDEFGHA* is the required octagon.

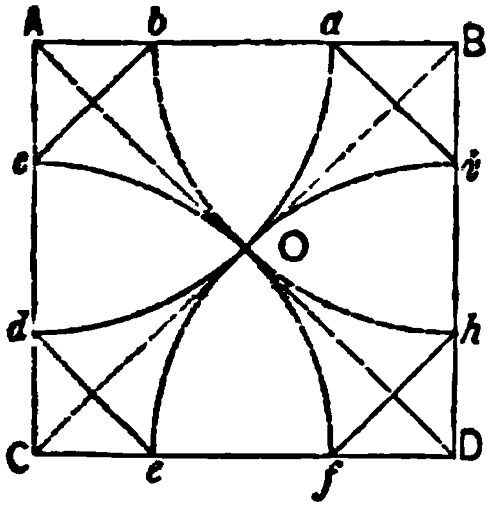

Fig. 77. Square and Inscribed Regular Octagon

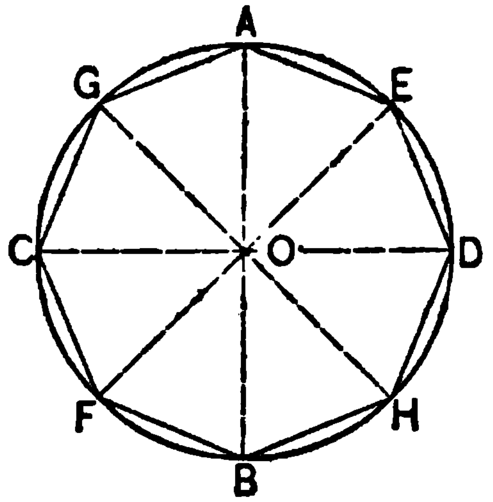

Fig. 78. Circle and Inscribed Regular Octagon

Problem 27. To construct a regular octagon in a square (Fig. 77).

Draw the diagonals *AD* and *BC* and from *A*, *B*, *C* and *D*, with a radius equal to *AO*, describe arcs cutting the sides of the square in *a*, *b*, *c*, *d*, *e*, *f*, *h* and *i*. Draw *ai*, *hf*, *ed* and *cb*. *aihfedcba* is the required octagon.

Problem 28. To inscribe a regular octagon in a circle (Fig. 78).

Draw two diameters, AB and CD, at right-angles to each other. Bisect angles AOD and AOC by the diameters EF and GH. $AEDHBFCGA$ is required octagon.

Problem 29. To inscribe a circle within a regular polygon.

First. When the polygon has an even number of sides, as in Fig. 79. B two opposite sides at A and B, draw AB and bisect it at C by a diagonal, connecting two opposite angles, as D and E. The circle drawn with a ra and with C as a center is the inscribed circle required.

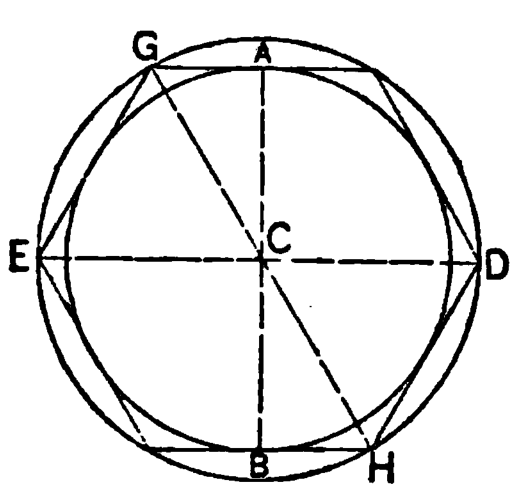

Fig. 79. Regular Polygon, Even Number of Sides, with Inscribed and Circumscribed Circles

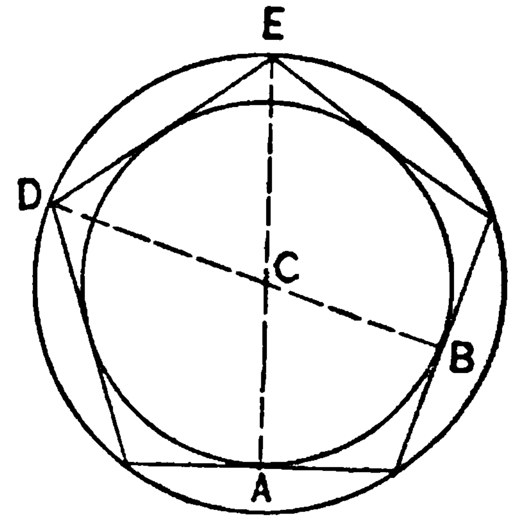

Fig. 80. Regular Polygon. Odd Number of Sides, with Inscribed and Circumscribed Circles

Second. When the number of sides is odd, as in Fig. 80. Bisect two of adjacent sides as at A and B, and draw lines, AE and BD, to the opposite an and intersecting at C. The circle drawn with C as a center and CA as a ra is the inscribed circle required.

Problem 30. To draw a circumscribing circle around a regular polygon.

First. When the number of sides is even, as in Fig. 79. Draw two diago from opposite angles, as ED and GH, intersecting at C. The circle drawn C as a center and with CD as a radius is the circumscribing circle required.

Second. When the number of sides is odd, as in Fig. 80. Determine center, C, as in the last problem. The circle drawn with C as a center and as a radius, is the circumscribing circle required.

Problems on the Ellipse, the Parabola, the Hyperbola and the Cycloid

The Ellipse

Problem 31. To describe an ellipse, the length and breadth, or the two a being given.

First Method (Fig. 81), the two axes, AB and CD, being given. On AB CD as diameters and from the same center, O, describe the circles $AGBH$ $CLDK$. Take any convenient number of points on the circumference of outer circle, as b, b', b'', etc., and from them draw lines to the center, O, cutt the inner circle at the points a, a', a'', etc., respectively. From the poi b, b', etc., draw lines parallel to the shorter axis CD; and from the point

d, etc., draw lines parallel to the longer axis AB, and intersecting the first set of lines at c, c', c'', etc. These last points will be points in the ellipse, and by determining a sufficient number of them, the ellipse can be drawn.

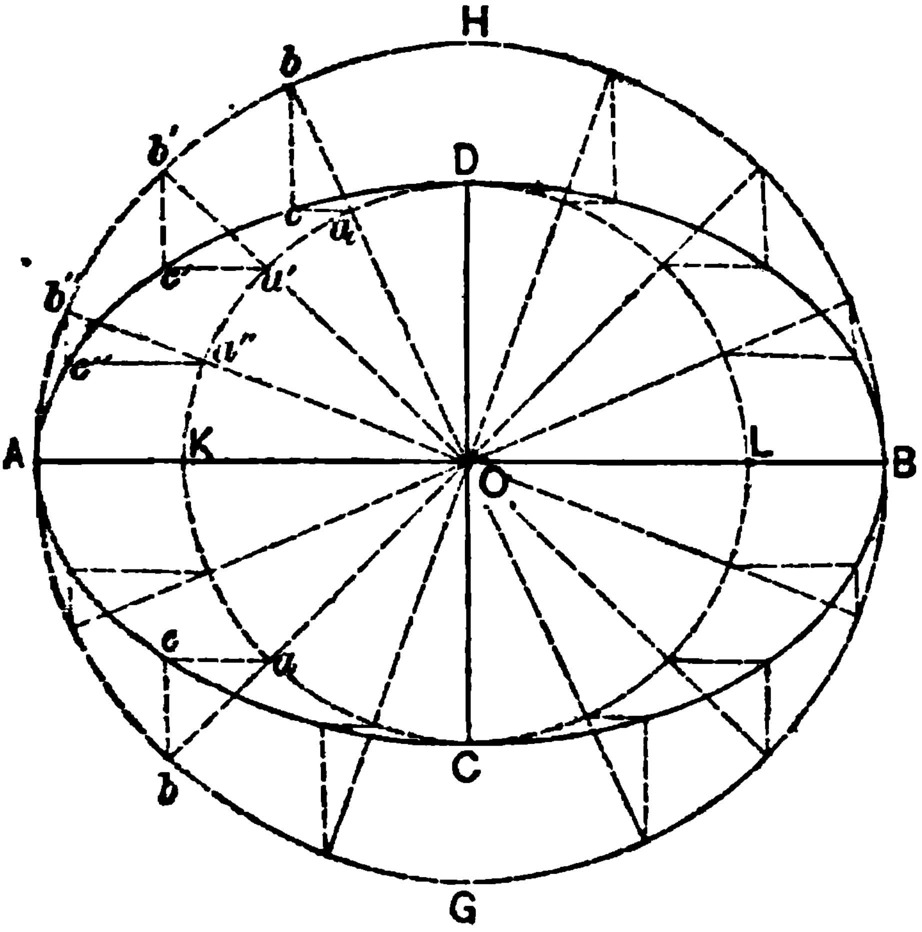

Fig. 81. Ellipse Described on Given Axes.

Second Method (Fig. 82). Take the straight-edge, made of a stiff piece of paper, cardboard or wood, and from some point as a, mark off ab equal to half the shorter diameter CD, and ac equal to half the longer diameter AB. Place the straight-edge so that the point b is on the longer and the point c on the shorter diameter. Then will the point a be over a point in the ellipse. Make on the paper a dot at a and move the straight-edge around, always keeping the points b and c over the major and minor axes respectively. In this way any number of points in the ellipse may be determined and the ellipse drawn.

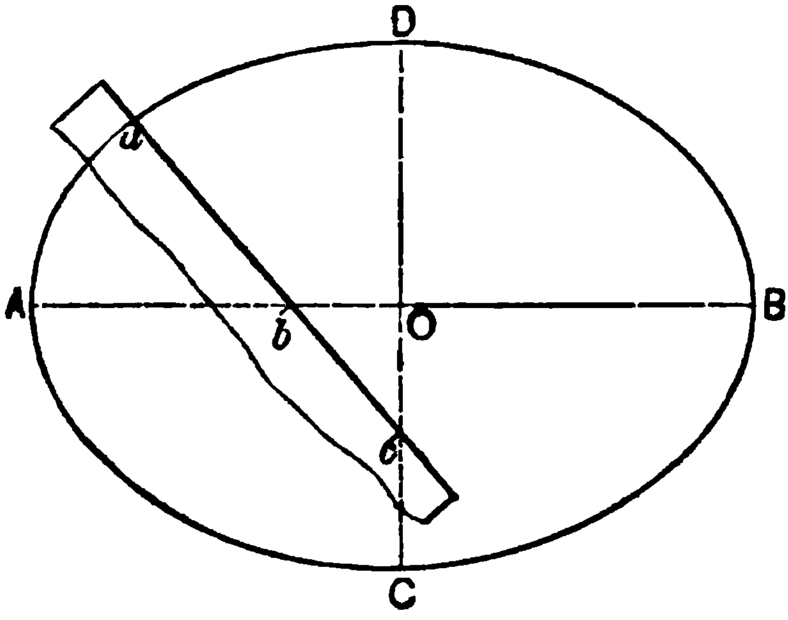

Fig. 82. Ellipse Described with Straight-Edge

Third Method (Fig. 83). Given, the two axes, AB and CD. From the point D as a center, and a radius AO, equal to one-half of AB, describe an arc cutting AB at F and F'. These two points are called the foci of the ellipse.

Note. One property of the ellipse is, that the sums of the distances of any two points on the circumference from the foci are the same. Thus $F'D + DF =$ [illegible] or $F'G + GF$.

Fix two pins in the axis AB at F and F' and loop upon them a thread, or cord equal in length, when fastened to the pins, to AB, so as, when stretched as per dotted line FDF', will just reach to the extremity D of the short axis. Place a pencil-point inside the cord, as at E, and move the pencil along, keeping the cord stretched tight. The pencil-point will trace the ellipse required.

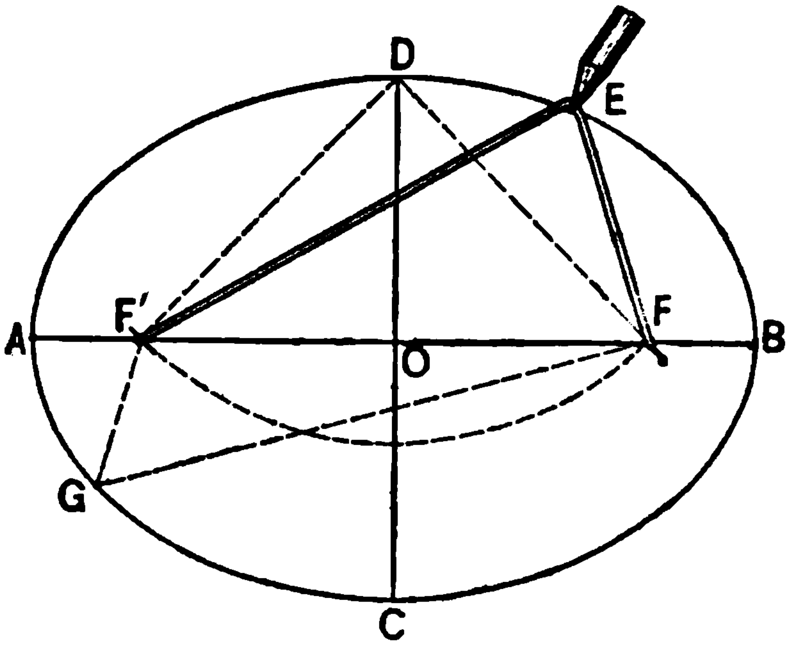

Fig. 83. Ellipse Described with String and Pencil

Problem 32. To draw a tangent to an ellipse at a given point on the curve (Fig. 84).

Let it be required to draw a tangent at the point E on the ellipse shown. First determine the foci F and F' as in the third method for describing an ellipse, and from E draw lines EF and EF'. Prolong EF' to a, so that Ea equals EF. Bisect the angle aEF by describing arcs from a and F as centers, as shown at b, and through b draw a line through E. This line is the tangent required. If it is required to draw a line normal to the curve at E, as, for instance, the joint of an elliptical

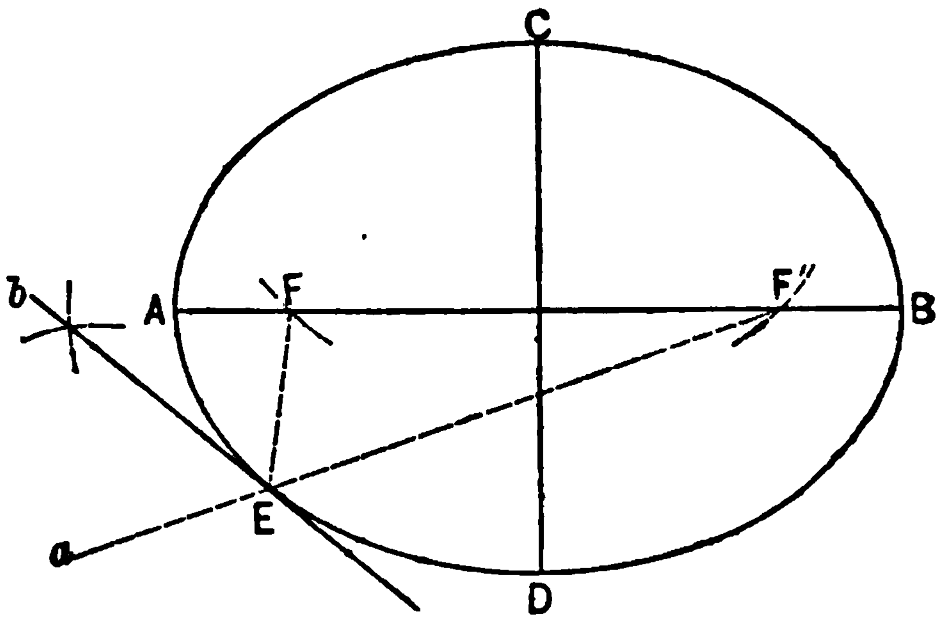

Fig. 84. Tangent Drawn to Point on Ellipse

arch, bisect the angle FEF', and draw the bisecting line through E, and it will be the normal to the curve and the proper line at that point for the joint of the elliptical arch.

Problem 33. To draw a tangent to an ellipse from a given point outside of the curve (Fig. 85).

From the given point T as a center, and with a radius equal to the distance to the nearer focus F, describe an arc of a circle. From F' as a center, and with a radius equal to the length of the longer axis of the ellipse, describe an arc cutting the circle just described at a and b. Draw lines from F' to a and b cutting the ellipse at E and G. Draw lines from T through E and G and these will be the tangents required.

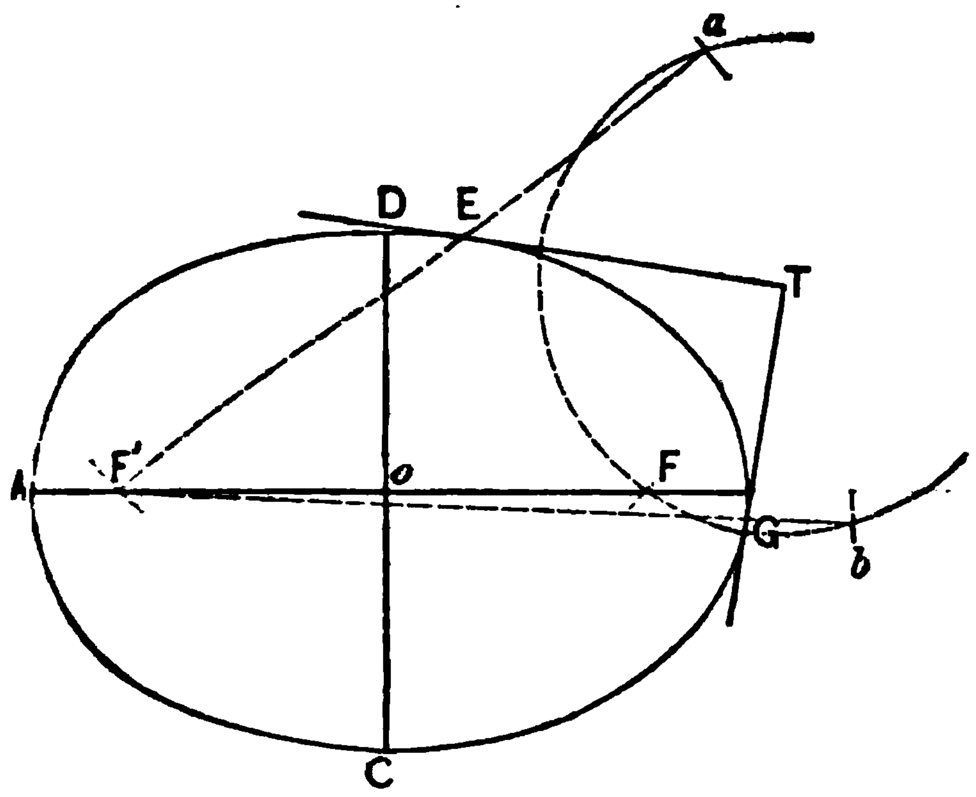

Fig. 85. Tangent Drawn to Ellipse from Point Outside

34. To describe an ellipse approximately, by means of circular arcs.
With arcs of two radii (Fig. 86). Take half the difference of the two
AB and *CD*, and set it off from the center *O* to *a* and *c* on *OA* and *OC*;
and on *AB* set off half *ac* from *a* to *d*; draw *di* parallel to *ac*; set off *Oe* equal
; join *ei* and draw *em* and *dm* parallel respectively to *id* and *ie*. With

point on the left
side of the ellipse.
method results
curve which is s
fuller at the haunches than the curve drawn by the preceding method

Second. With arcs of three radii (Fig. 88). On the transverse or majo

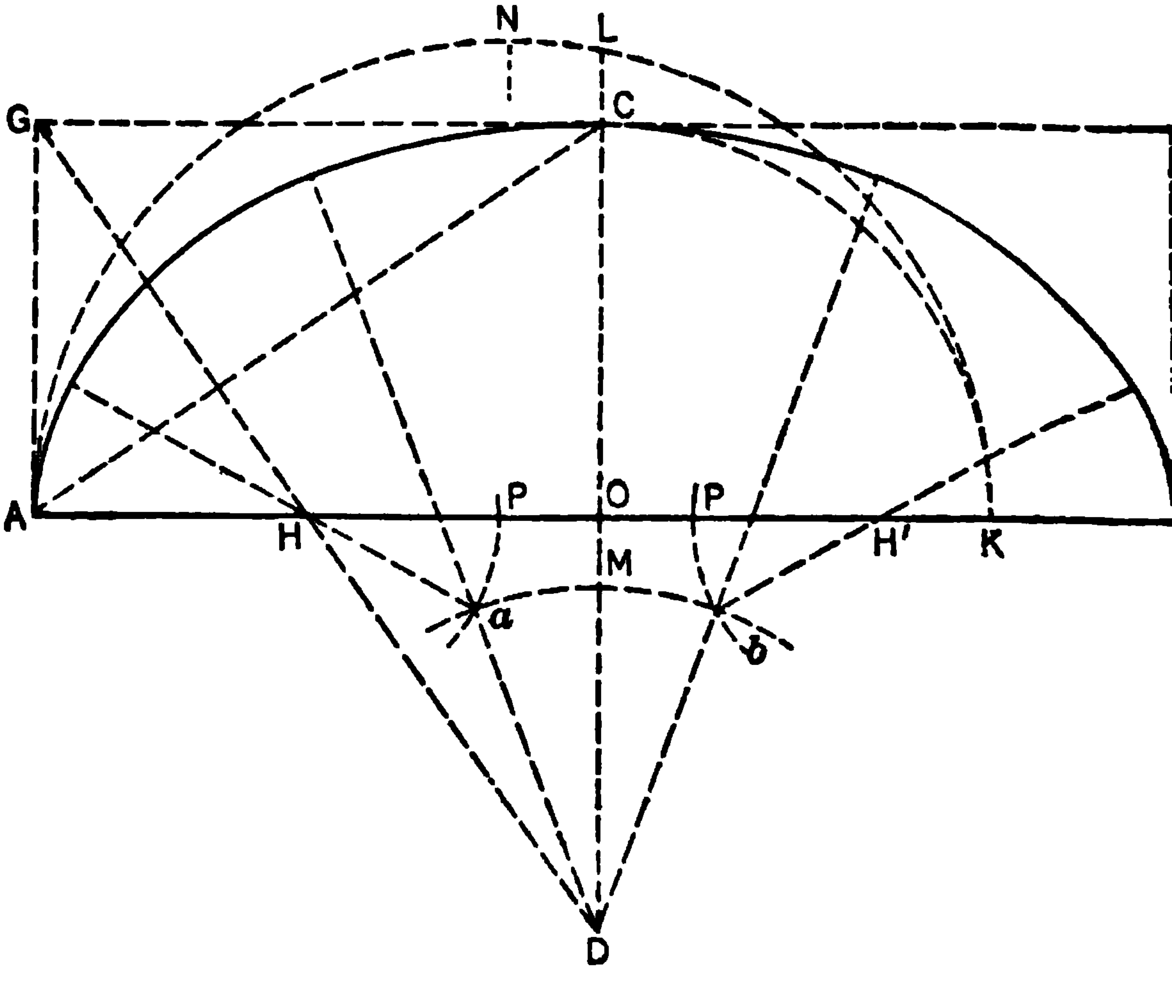

Fig. 88. Ellipse Described with Circular Arcs of Three Radii

AB draw the rectangle $AGEBA$, equal in height to OC, half the conju
minor axis. Draw AC and draw GD perpendicular to AC. Set off OK e

on *AK* as a diameter describe the semicircle *ANK*. Extend *OC* to *D*. Set off *OM* equal to *CL*, and with *D* as a center and with a radius describe an arc. With *A* and *B* as centers and with a radius *OL*, cut *AB* at *P*. From *H* as a center, and with a radius *HP*, cut the arc *ab* at *a*. *b* are determined in like manner. The points *H*, *a*, *D*, *b* and *H'*, are centers of the arcs required.

...the lines *aH*, *Da*, *Db*, and *bH'*, and thus determine the lengths of ... This method is practicable for all ellipses. It is often employed ..., stone arches and bridges.

The Parabola

...em 35. To describe a parabola when the vertex A, the axis AB and a ..., II, of the curve are given (Fig. 89).

...struct the rectangle *ABMCA*. Divide *MC* into any number of equal ..., four for instance. Divide *AC* in like manner. Connect *A*1, *A*2 and *A*3. ...gh 1', 2', 3', draw parallels to the axis *AB*. The intersections I, II and ... of these lines, are points in the required curve.

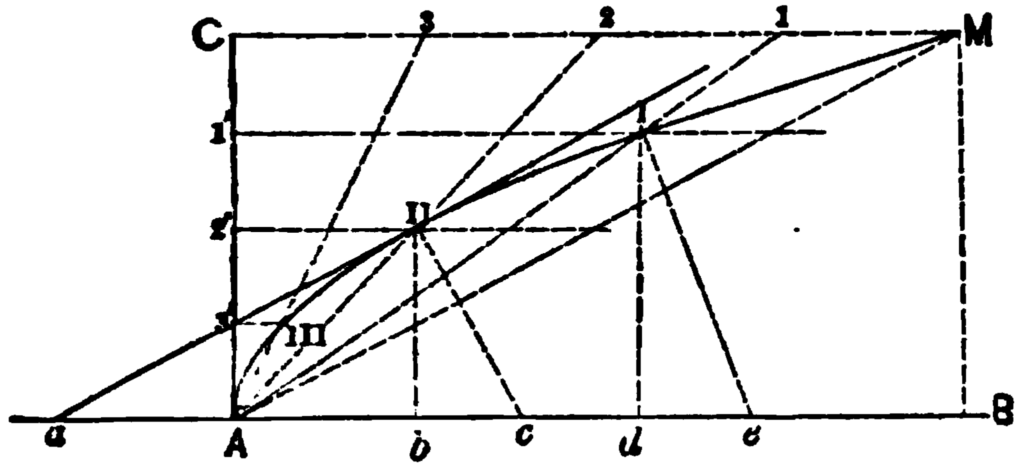

Fig. 89. Parabola and Tangent to Point on Parabola

...lem 36. To draw a tangent to a given point, II, of the parabola (Fig. 89).

...m the given point II let fall a perpendicular on the axis *AB* at *b*. Produce ...is to the left of *A*. Make *Aa* equal to *Ab*. A line drawn through *a* and ... the tangent required. The lines perpendicular to the tangent are called ...als.

...draw a normal to any point, as I, the tangent to any other point, II being ...

...w the normal II*c*. From I, let fall a perpendicular I*d*, on the axis *AB*. ...f *de* equal to *bc*. The line I*e* is the normal required. The tangent may be ...n at I by laying off a perpendicular to the normal I*e* at I.

The Hyperbola

...from any point, *P*, of an hyperbola, two straight lines are drawn to two ... points, as *F* and *F'*, the foci of the hyperbola, their DIFFERENCE is always ...same.

...lem 37. To describe an hyperbola when a vertex, a, the given difference ...d one of the foci, F are given (Fig. 90).

...w the axis *AB* of the hyperbola, with the given distance *ab* and the focus

F marked on it. From *b* lay off bF_1 equal to aF to determine the other fo

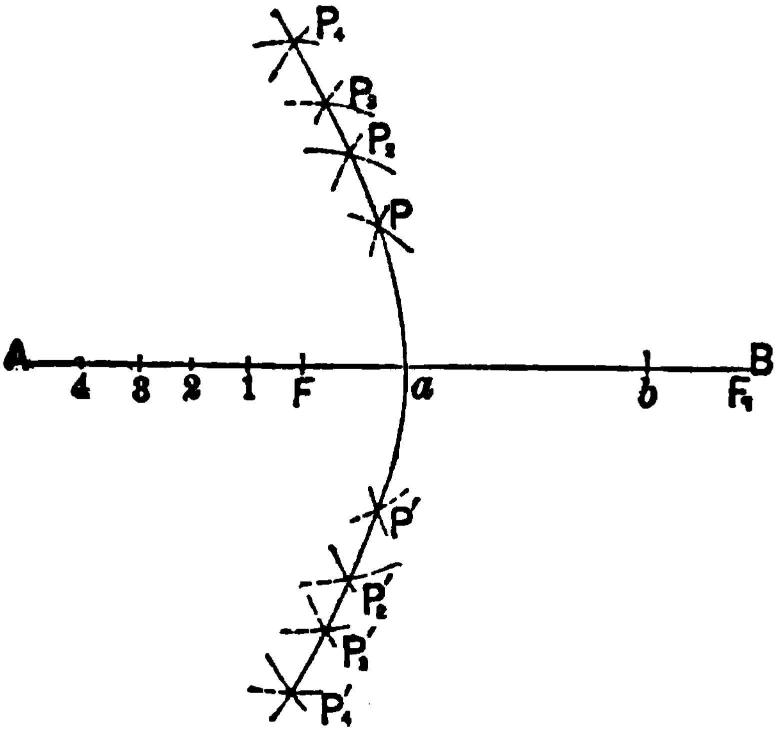

Fig. 90. Hyperbola Described

Take any point, as 1 and with $a1$ as a radius as a center, describe tw arcs above and below t With $b1$ as a radius, an a center, describe arcs those just described, at P'. Take several point 3 and 4, and determine t responding points P_2, P_4 in the same way curve passing through points is an hyperbola.

To draw a tangent point of an hyperbola, lines from the given p each of the foci and the angle thus formed bisecting line is the t required.

The Cycloid

The CYCLOID is the curve described by a point on the circumference of rolling in a straight line.

Problem 38. To describe a cycloid (Fig. 91).

Draw the straight line *AB*. Describe the generating circle tangent line at its middle point *D*, and through the center *C*, of the circle, draw t

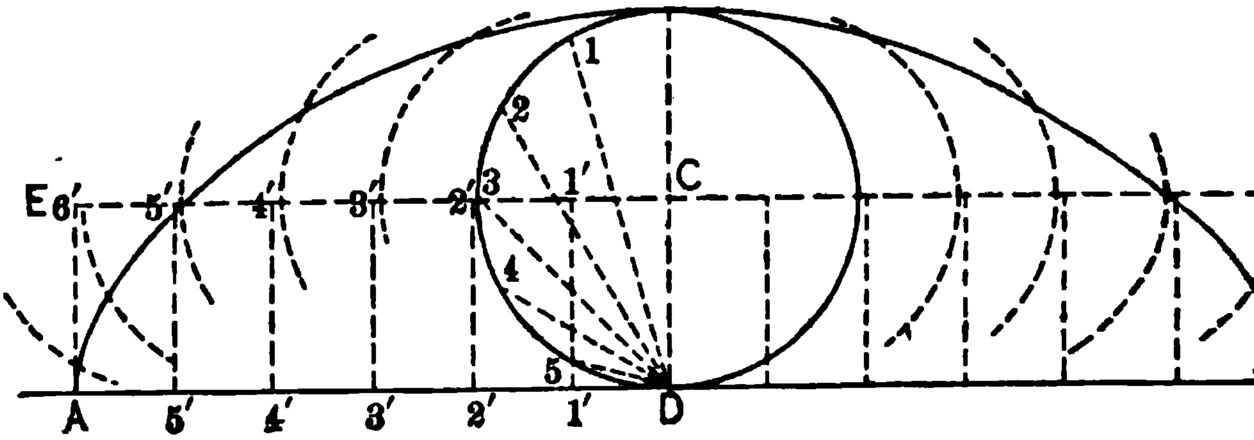

Fig. 91. Cycloid Described

EE parallel to *AB*. Let fall a perpendicular from *C* upon *AB*. Divide the circumference into any number of equal parts, for example, six. Lay off o and *CE* distances $C1'$, $1'2'$, etc., equal to the divisions of the circumfe Draw the chords $D1$, $D2$, etc. From the points $1'$, $2'$, $3'$, etc., on the lin with radii equal to the generating circle, describe arcs as shown. From points $1'$, $2'$, $3'$, $4'$, $5'$, etc., on the line *BA*, and with radii equal respectiv the chords $D1$, $D2$, $D3$, $D4$, $D5$, describe arcs cutting the preceding The intersections are points of the required cycloid.

Table of Chords. Radius = 1.0000

Lengths and Bevels of Hip-Rafters and Jack-Rafters

Method of Determining the Lengths and Bevels. The lines a (Fig. 92) represent the outside of the walls at the angle of a building; seat of the hip-rafter and *gf* of a jack-rafter. Draw *eh* at right-ang and make it equal to the rise of the roof; join *b* and *h* and *hb* will be t of the hip-rafter. Through *e* draw *di* at right-angles to *bc*. With *b* as

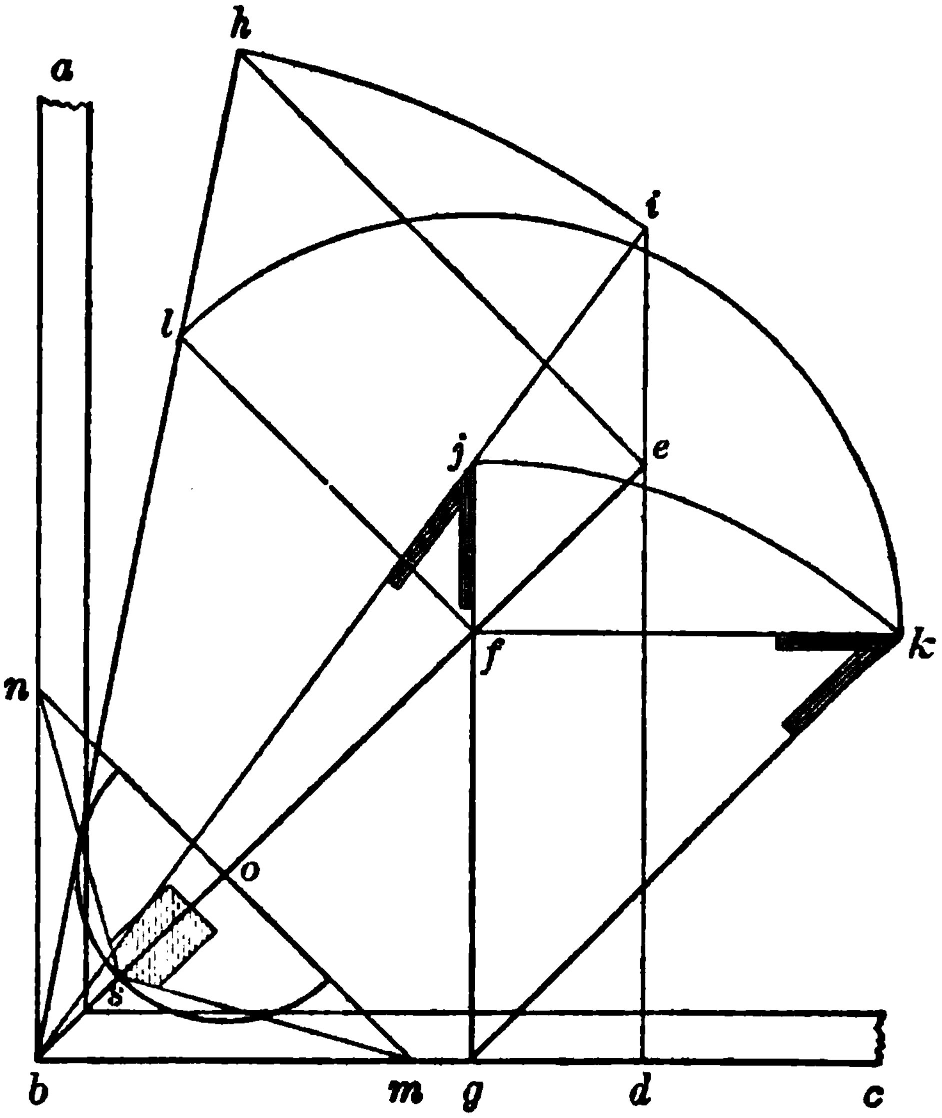

Fig. 92. Lengths and Bevels of Hip-rafters and Jack-rafters

and with the radius *bh*, describe the arc *hi*, cutting *di* in *i*. Join *b* an extend *gf* to meet *bi* in *j*; then *gj* is the length of the jack-rafter. The l each jack-rafter is found in the same manner, by extending its seat to line *bi*. From *f* draw *fk* at right-angles to *fg*; also *fl* at right-angles to *be*. *fk* equal to *fl* by the arc *lk*, or make *gk* equal to *gj* by the arc *jk*; then t at *j* is the TOP BEVEL of the jack-rafters, and the angle at *k* the DOWN BE

Backing of the Hip-Rafter. At any convenient point in *be* (Fig. 9 draw *mn* at right-angles to *be*. From *o* describe a circle, tangent to *bh*, *bc* in *s*. Join *m* and *s* and *n* and *s*. The lines *ms* and *ns* form at *s* the angle for beveling the top of the hip-rafter.

5. TRIGONOMETRY

It is not the purpose of the author to teach the principles or uses of tri etry; but for the benefit of those readers who have already acquired a kno of this science, the following convenient formulas and tables of natura cosines, tangents and cotangents have been inserted. To those who kno to apply these trigonometric functions, they will often be found of gre venience and utility. These tables are taken, by permission, from Searle' Engineering, John Wiley & Sons, Inc., publishers.

Trigonometric Functions

A (Fig. 93) = angle BAC = arc BF and let the radius $AF = AB = AH = 1$ then

$\sin A = BC$

$\cos A = AC$

$\tan A = DF$

$\cot A = HG$

$\sec A = AD$

$\operatorname{cosec} A = AG$

$\operatorname{versin} A = CF = BE$

$\operatorname{covers} A = BK = HL$

$\operatorname{exsec} A = BD$

$\operatorname{coexsec} A = BG$

$\operatorname{chord} A = BF$

$\operatorname{chord} 2A = BI = 2\,BC$

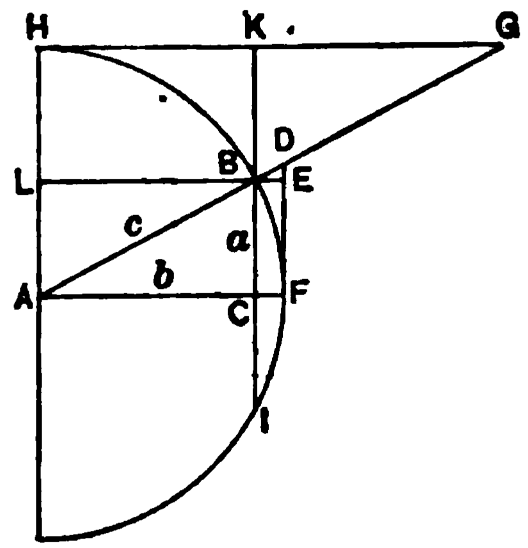

Fig. 93. Functions of Right-angled Triangle

the right-angled triangle ABC (Fig. 93) let $AB = c$, $AC = b$ and $BC = a$

$$\sin A = \frac{a}{c} = \cos B$$

$$\cos A = \frac{b}{c} = \sin B$$

$$\tan A = \frac{a}{b} = \cot B$$

$$\cot A = \frac{b}{a} = \tan B$$

$$\sec A = \frac{c}{b} = \operatorname{cosec} B$$

$$\operatorname{cosec} A = \frac{c}{a} = \sec B$$

$$\operatorname{vers} A = \frac{c-b}{c} = \operatorname{covers} B$$

$$\operatorname{exsec} A = \frac{c-b}{b} = \operatorname{coexsec} B$$

$$\operatorname{covers} A = \frac{c-a}{c} = \operatorname{versin} B$$

$$\operatorname{coexsec} A = \frac{c-a}{a} = \operatorname{exsec} B$$

(11) $a = c \sin A = b \tan A$

(12) $b = c \cos A = a \cot A$

(13) $c = \dfrac{a}{\sin A} = \dfrac{b}{\cos A}$

(14) $a = c \cos B = b \cot B$

(15) $b = c \sin B = a \tan B$

(16) $c = \dfrac{a}{\cos B} = \dfrac{b}{\sin B}$

(17) $a = \sqrt{(c+b)\,(c-b)}$

(18) $b = \sqrt{(c+a)\,(c-a)}$

(19) $c = \sqrt{a^2 + b^2}$

(20) $C = 90° = A + B$

(21) $\text{area} = \dfrac{ab}{2}$

Solution of Oblique Triangles

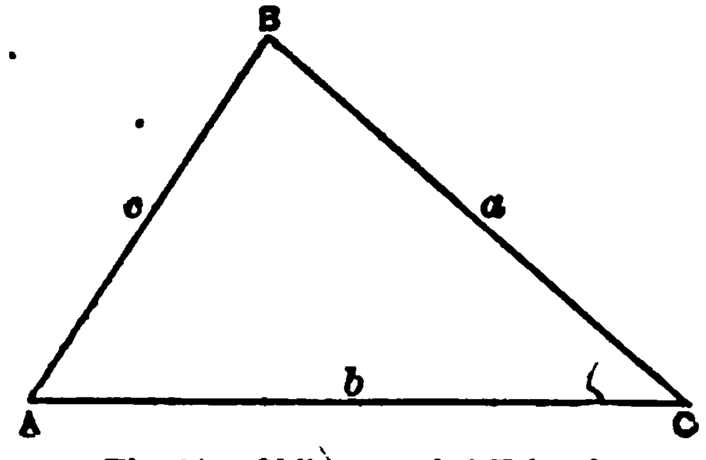

Fig. 94. Oblique-angled Triangle

	Given	Required	Formulas
(22)	A, B, a	C, b, c	$C = 180° - (A + B)$ $\qquad b = \dfrac{a}{\sin A} \cdot \sin B$ $c = \dfrac{a}{\sin A} \sin (A + B)$
(23)	A, a, b	B, C, c	$\sin B = \dfrac{\sin A}{a} \cdot b$ $\qquad C = 180° - (A + B$ $c = \dfrac{a}{\sin A} \cdot \sin C$
(24)	C, a, b	$\frac{1}{2}(A + B)$	$\frac{1}{2}(A + B) = 90° - \frac{1}{2}C$
(25)	....	$\frac{1}{2}(A - B)$	$\tan \frac{1}{2}(A - B) = \dfrac{a - b}{a + b} \tan \frac{1}{2}(A + B)$
(26)	....	A, B	$A = \frac{1}{2}(A + B) + \frac{1}{2}(A - B)$ $B = \frac{1}{2}(A + B) - \frac{1}{2}(A - B)$
(27)	....	c	$c = (a + b) \dfrac{\cos \frac{1}{2}(A + B)}{\cos \frac{1}{2}(A - B)} = (a - b) \dfrac{\sin \frac{1}{2}(A}{\sin \frac{1}{2}(A}$
(28)	....	Area	$K = \frac{1}{2} ab \sin C$
(29)	a, b, c	A	Let $s = \frac{1}{2}(a + b + c)$; $\quad \sin \frac{1}{2}A = \sqrt{\dfrac{(s - b)(}{bc}}$
(30)	....	....	$\cos \frac{1}{2}A = \sqrt{\dfrac{s(s - a)}{bc}}$; $\quad \tan \frac{1}{2}A = \sqrt{\dfrac{(s - b)(}{s(s -}}$
(31)	....	....	$\sin A = \dfrac{2\sqrt{s(s - a)(s - b)(s - c)}}{bc}$ $\text{vers } A = \dfrac{2(s - b)(s - c)}{bc}$
(32)	....	Area	$K = \sqrt{s(s - a)(s - b)(s - c)}$
(33)	A, B, C, a	Area	$K = \dfrac{a^2 \sin B \sin C}{2 \sin A}$

Oblique Triangles. General Formulas

$$\sin A = \frac{1}{\operatorname{cosec} A} = \sqrt{1-\cos^2 A} = \tan A \cos A$$

$$\sin A = 2 \sin \tfrac{1}{2} A \cos \tfrac{1}{2} A = \operatorname{vers} A \cot \tfrac{1}{2} A$$

$$\sin A = \sqrt{\tfrac{1}{2} \operatorname{vers} 2A} = \sqrt{\tfrac{1}{2}(1-\cos 2A)}$$

$$\cos A = \frac{1}{\sec A} = \sqrt{1-\sin^2 A} = \cot A \sin A$$

$$\cos A = 1 - \operatorname{vers} A = 2\cos^2 \tfrac{1}{2} A - 1 = 1 - 2\sin^2 \tfrac{1}{2} A$$

$$\cos A = \cos^2 \tfrac{1}{2} A - \sin^2 \tfrac{1}{2} A = \sqrt{\tfrac{1}{2} + \tfrac{1}{2}\cos 2A}$$

$$\tan A = \frac{1}{\cot A} = \frac{\sin A}{\cos A} = \sqrt{\sec^2 A - 1}$$

$$\tan A = \sqrt{\frac{1}{\cos^2 A} - 1} = \frac{\sqrt{1-\cos^2 A}}{\cos A} = \frac{\sin 2A}{1+\cos 2A}$$

$$\tan A = \frac{1-\cos 2A}{\sin 2A} = \frac{\operatorname{vers} 2A}{\sin 2A} = \operatorname{exsec} A \cot \tfrac{1}{2} A$$

$$\cot A = \frac{1}{\tan A} = \frac{\cos A}{\sin A} = \sqrt{\operatorname{cosec}^2 A - 1}$$

$$\cot A = \frac{\sin 2A}{1-\cos 2A} = \frac{\sin 2A}{\operatorname{vers} 2A} = \frac{1+\cos 2A}{\sin 2A}$$

$$\cot A = \frac{\tan \tfrac{1}{2} A}{\operatorname{exsec} A}$$

$$\operatorname{vers} A = 1 - \cos A = \sin A \tan \tfrac{1}{2} A = 2\sin^2 \tfrac{1}{2} A$$

$$\operatorname{vers} A = \operatorname{exsec} A \cos A$$

$$\operatorname{exsec} A = \sec A - 1 = \tan A \tan \tfrac{1}{2} A = \frac{\operatorname{vers} A}{\cos A}$$

$$\sin \tfrac{1}{2} A = \sqrt{\frac{1-\cos A}{2}} = \sqrt{\frac{\operatorname{vers} A}{2}}$$

$$\sin 2A = 2 \sin A \cos A$$

$$\cos \tfrac{1}{2} A = \sqrt{\frac{1+\cos A}{2}}$$

$$\cos 2A = 2\cos^2 A - 1 = \cos^2 A - \sin^2 A = 1 - 2\sin^2 A$$

$$\tan \tfrac{1}{2} A = \frac{\tan A}{1+\sec A} = \operatorname{cosec} A - \cot A = \frac{1-\cos A}{\sin A} = \sqrt{\frac{1-\cos A}{1+\cos A}}$$

$$\tan 2A = \frac{2\tan A}{1-\tan^2 A}$$

$$\cot \tfrac{1}{2} A = \frac{\sin A}{\operatorname{vers} A} = \frac{1+\cos A}{\sin A} = \frac{1}{\operatorname{cosec} A - \cot A}$$

$$\cot 2A = \frac{\cot^2 A - 1}{2 \cot A}$$

(57) $\operatorname{vers} \frac{1}{2} A = \dfrac{\frac{1}{2} \operatorname{vers} A}{1 + \sqrt{1 - \frac{1}{2} \operatorname{vers} A}} = \dfrac{1 - \cos A}{2 + \sqrt{2(1 + \cos A)}}$

(58) $\operatorname{vers} 2A = 2 \sin^2 A$

(59) $\operatorname{exsec} \frac{1}{2} A = \dfrac{1 - \cos A}{(1 + \cos A) + \sqrt{2(1 + \cos A)}}$

(60) $\operatorname{exsec} 2A = \dfrac{2 \tan^2 A}{1 - \tan^2 A}$

(61) $\sin (A \pm B) = \sin A \cos B \pm \sin B \cos A$

(62) $\cos (A \pm B) = \cos A \cos B \mp \sin A \sin B$

(63) $\sin A + \sin B = 2 \sin \frac{1}{2} (A + B) \cos \frac{1}{2} (A - B)$

(64) $\sin A - \sin B = 2 \cos \frac{1}{2} (A + B) \sin \frac{1}{2} (A - B)$

(65) $\cos A + \cos B = 2 \cos \frac{1}{2} (A + B) \cos \frac{1}{2} (A - B)$

(66) $\cos B - \cos A = 2 \sin \frac{1}{2} (A + B) \sin \frac{1}{2} (A - B)$

(67) $\sin^2 A - \sin^2 B = \cos^2 B - \cos^2 A = \sin (A + B) \sin (A - B)$

(68) $\cos^2 A - \sin^2 B = \cos (A + B) \cos (A - B)$

(69) $\tan A + \tan B = \dfrac{\sin (A + B)}{\cos A \cos B}$

(70) $\tan A - \tan B = \dfrac{\sin (A - B)}{\cos A \cos B}$

PART II

RENGTH OF MATERIALS AND STABILITY OF STRUCTURES

INTRODUCTION

LANATION OF SUBJECT-MATTER AND NOTATION

1. Introduction to Part II

ject-Matter of Part II. In the thirty-one chapters of Part II are the necessary rules, formulas and data for computing the strength and ity of all ordinary forms of building-construction, whether of wood, steel, te or masonry, and in fact of all but the more intricate problems of steel uction, with which few architects care to cope, and which, indeed, are especially within the province of the engineer.

e Rules and Formulas have been reduced to their simplest forms, and, eral, require only an elementary knowledge of mathematics to understand . The application of the formulas is explained and in most cases their ation, and it is believed that the formulas, constants and working stresses epresentative of conservative and approved contemporary practice.

nstants and Working Stresses. In the use of constants for the strength terials, the authors and editors have been guided by the practice of leading tural engineers, by the available records of tests and by their own expe- e of many years as practicing and consulting architects and engineers. arying conditions of building-construction have been taken into account n attempt made to adapt the values to the practical conditions usually ning such construction. Every possible precaution has been taken to nt the misapplication of rules and formulas and to insure absolute safety ut undue waste of materials.

bles. Much thought and labor have been expended on the preparation e numerous tables, to insure their accuracy and to arrange them in the convenient form for use by architects and builders. Many of these tables computed by the authors and editors, all have been carefully verified, and believed that they may be used with perfect confidence. In all cases, un- therwise noted, they give the same values that would be obtained by g the formulas specially referred to, while they afford a great saving of and labor and reduce to a minimum the danger of errors in making the ary computations.

atment of the Subject. Owing to the nature of the subjects treated he large number of pages required to include them all in one book of refer- some forms of construction are treated rather briefly. The intention is to the data needed for immediate use rather than a complete discussion of e principles involved. Those who wish more complete discussions of s' work, carpenters' work, steelwork, etc., are referred to treatises on branches of building-construction. References are made in the different ers to various other books and periodicals containing more complete ation on some of the subjects. The thirty-one chapters of Part II principally with foundations, walls and piers, arches, columns, beams girders, floors, mill-construction, fireproofing, reinforced-concrete con- tion, roof-trusses, wind-bracing, and domes and vaults.

2. Explanation of the Notation or Symbols used in Part

Besides the usual mathematical signs and characters in general use lowing abbreviations and symbols are frequently used:

- A area of cross-section; also, a constant used in Chapter XVI a to 1/18 the safe unit fiber-stress;
- $a, b, c, \ldots m$, etc., known or given distances;
- b breadth, as of beams;
- C coefficient of strength;
- c normal distance from neutral axis of cross-section of beam distant fiber in same;
- d diameter, as of rivets; exterior diameter; depth, as of beams;
- d_1 interior diameter;
- E modulus of elasticity;
- E_s, E_c modulus of elasticity for steel and concrete respectively (inforced concrete);
- e total deformation or change in length, as in a bar;
- F shearing-modulus of elasticity;
- f maximum deflection for a beam;
- h distance between parallel axes for moments of inertia;
- I moment of inertia about a line;
- I/c section-modulus or section-factor;
- J polar moment of inertia;
- J' polar moment of inertia of bolts about shaft-axis;
- K total elastic resistance of a bar; resilience, work; also, a facto stant used in formulas for reinforced concrete;
- l length; span of a beam;
- M bending moment;
- M_{max} maximum bending moment;
- M_1, M_2, etc., bending moments at supports of beams;
- M_r or SI/c moment of resistance;
- n number of loads, spans, etc.;
- P external force; concentrated load;
- P_1, P_2, P_3, etc., concentrated loads on beams;
- p pitch of rivets; eccentricity of load on column; ratio of cros of steel to cross-section of beam (reinforced concrete);
- r radius of curvature; radius; radius of gyration; ratio of E_s to E_c for concrete (reinforced concrete);
- R_1, R_2, R_3, etc., reactions at the supports of a beam;
- S unit stress, with subscripts t, c and s for unit stress in tensi pression and shear, respectively;
- S_b buckling resistance in webs of steel beams;
- S_h horizontal unit shearing-stress in beams;
- S_e elastic limit;
- S_f modulus of rupture, or computed flexural strength;
- t_1, t_2, etc., thicknesses;
- V vertical shear;
- W weight of a bar or beam; total uniform load on beam (may weight of beam);
- wl total uniform load on a beam (may include weight of beam);
- w weight of a cubic unit of material; uniform load on beam, p unit of length;

* See, also, page 3 of Part I.

x, y, z, variable distances;
a, b, etc., material constants;
ϕ constant depending upon material;
θ an angle.

[Gre]ek letters are used generally for signs of operation, for abstract numbers [or] for angles. Σ is employed as a symbol of summation.

[Th]e following are the Greek letters most in use:

α Alpha,	β Beta,	ϵ Epsilon,	η Eta,
θ Theta,	κ Kappa,	λ Lambda,	μ Mu,
ν Nu,	π Pi,	ρ Rho,	σ Sigma,
τ Tau,	ϕ Phi,	ψ Psi,	ω Omega.

[Not]e. In a few places in the book it has been considered necessary or advis[able] by some of the associate editors to give a different meaning to one or [more] of the above symbols or to introduce different symbols for the meanings [give]n in the list, but in all such cases the new symbols or meanings have been [c]learly indicated.

[Th]e term BREADTH is used to denote the horizontal thickness of a beam or [the s]maller dimension of the cross-section of a rectangular column, post or [tie], and is always measured in inches unless expressly stated otherwise.

[Th]e term DEPTH denotes the vertical height of a beam or girder, and is always [measur]ed in inches unless expressly stated otherwise.

[Th]e term LENGTH denotes the distance between supports and is always meas[ured i]n feet unless expressly stated otherwise.

[Ab]breviations. In order to shorten the formulas, the tabulations of computa[tions], etc., and throughout the text generally, to economize space, the units of [measu]rement are generally abbreviated. For example, foot and feet are abbre[viate]d ft; inch and inches, in; pound and pounds, lb; square, sq; cubic, cu; [...]; in; inch-pound or inch-pounds, in-lb; foot-pound or foot-pounds, ft-lb; [ounce]s, oz; horse-power, h.p.; gallons, gal; etc.; and no periods are placed after [the] abbreviations, except at the ends of sentences. Where the word TON is [used i]n this volume, it always means the net ton of 2 000 lb.

CHAPTER I

EXPLANATION OF TERMS USED IN ARCHITECT ENGINEERING

By
THOMAS NOLAN
PROFESSOR OF ARCHITECTURAL CONSTRUCTION, UNIVERSITY OF PENNS

1. Definitions of Some of the Terms Used in the Mechani Materials *

Terms Used in Architectural Engineering. The following te quently occur in discussions of the principles of architectural engineer an understanding of their meaning is essential.

Mechanics is the branch of physics that treats of the phenomena ca the action of forces on material bodies.

Applied Mechanics treats of the laws of mechanics as applied to c tion in the useful arts, as in beams, trusses, arches, etc.

Mechanics of Materials treats of the effects of forces in causing in the size and shape of bodies.

Rest is the relation that exists between two points when the strai joining them does not change in length or direction. A body is at rest re to a point when any point in the body is at rest relatively to the first-me point.

Motion is the relation that exists between two points when the strai joining them changes in length or direction, or in both. A body mov tively to a point when any point in the body moves relatively to the fir tioned point.

Force is that which changes, or tends to change, the state of rest or of the body acted upon. It is a cause regarding the essential nature o we are ignorant. In the mechanics of materials we do not deal with the of forces, but only with the laws of their action.

Equilibrium is that condition of a body in which the forces acting balance or neutralize each other; or, it is that condition of a force-sy which the resultant of the force-system is zero.

Statics is the branch of Mechanics that treats of the conditions of equil It is divided into:

(1) Statics of rigid bodies.

(2) Statics of practically incompressible fluids.

In building-construction we have to deal only with the former.

Structures are artificial constructions in which all the parts are inte be in equilibrium and at rest relatively to each other, as in the case of a truss or roof-truss. They consist of two or more solid bodies, generally PIECES or MEMBERS, which are connected at different parts of their s called JOINTS.

* In addition to the terms defined here, many others are defined in the cha Part II, and especially in Chapters VI, IX, X, XIV, XV, XVI, XX and XXIV.

general there are three conditions of equilibrium in a structure.

(1) The external forces acting upon the whole structure must balance each other. These forces are:

(a) The weight of the structure;

(b) The loads it carries;

(c) The upward supporting forces, reactions or resistances under or around foundations.

(2) The forces acting upon each piece of the structure must balance each other. These forces are, for each piece:

(a) The weight of the piece;

(b) The loads it carries;

(c) The resistances or reactions at its joints.

(3) The forces acting upon each of the parts into which any piece may be supposed to be divided must balance each other.

The **Stability of a Structure** requires the fulfilment of conditions (1) and (2), that is, the ability of the structure to resist the DISPLACEMENT of any of its parts.

The **Strength of a Piece or Member** consists in the fulfilment of condition (3), that is, the ability of a piece to resist BREAKING.

The **Stiffness of a Piece or Member** consists in the ability of a piece to resist BENDING.

The **Theory of Structures** is divided into two parts:

(1) That which treats of strength and stiffness, dealing only with single pieces and generally known as the STRENGTH OF MATERIALS or the MECHANICS OF MATERIALS, before defined.

(2) That which treats of stability, dealing with the structures themselves.

Stress is an internal force that resists a change in shape or size caused by external forces. When the applied external forces reach certain intensities internal stresses hold them in equilibrium.

The **Intensity of a Stress** is measured by the UNIT STRESS. (See Unit Stress.) The INTENSITY OF THE STRESS per square inch on any normal surface of a solid is the total stress divided by the area of the section in square inches. Thus, if a bar 10 ft long and 2 in square has a load of 8 000 lb pulling in the direction of its length, the stress on any normal section of the bar is 8 000 lb; and the intensity of the stress per square inch is 8 000 lb/4 sq in = 2 000 lb per sq in.

Deformation.* When a solid body is acted upon by an external force an alteration takes place in the volume and shape of the body, and this alteration is called the DEFORMATION. In the case of the bar given above, the deformation is the amount that the bar stretches under its load.

The **Ultimate Strength** is the highest unit stress a piece of material can sustain and it is the unit stress at or just before rupture.

The **Working Unit Stress** is the ultimate stress divided by the factor of safety.

The **Safe Load** is the load that a piece can support without exceeding the working unit stresses.

* In mechanics the term STRAIN is now synonymous with the term DEFORMATION. On account of the tendency to confuse the terms STRAIN and STRESS the term DEFORMATION is used to denote change in shape and the term STRAIN is omitted in all discussions in the Pocket-Book.

The Factor of Safety * of a piece of material under stress is the r the ultimate strength of the material to the actual unit stress on the s area; or it is the number by which the ultimate unit stress must be divi give the working unit stress. In designing a piece of material to sustair tain load, it is required that it shall be perfectly safe under all circumst and hence it is necessary to make an allowance for any defects in the ma workmanship, etc. It is obvious, that, for materials of different compo different factors of safety are required. Thus, steel being more homog than wood and less liable to defects, does not require as high a factor of Again, different kinds of stresses require different factors of safety. T long wooden column or strut requires a higher factor of safety than a w beam. As the factors of safety thus vary for different kinds of stress materials, the proper factors for the different kinds of stresses and conditio given in considering the resistance of the various materials to those s under varying conditions.

The Unit Stress is the stress on a unit of section-area, and is usually exp in pounds per square inch. (See Intensity of Stress.)

Dead Loads and Live Loads. The term DEAD LOAD means a load applied and increased gradually and that finally remains constant, such weight of a structure itself.

The term LIVE LOAD means a load that is applied suddenly and causes tions, such as a train traveling over a railway bridge. It has been fou experience that the effect of a live load on a beam or other piece of m has twice the destructive tendency of a dead load of the same magnit intensity. Hence a piece of material designed to carry a live load shoul a factor of safety twice as large as one designed to carry a dead load load due to a crowd of people walking on a floor is usually considered to p an effect which is a mean between that of a dead load and a live load, suitable factor of safety is adopted accordingly. In municipal ordinanc laws relating to the allowable loads for floors, the loads to be supported floors, exclusive of their inherent construction and stationary fixtures, ar erally referred to as the LIVE LOADS no matter of what they may consis the term does not have the exact significance given to it by many en and as explained in the paragraph above.

The Modulus of Rupture or Computed Flexural Strength is the of the UNIT FIBER-STRESS S, computed from the flexure-formula M = when a beam is ruptured under a transverse load. Its value is interm between the ultimate tensile and compressive strengths of a material.

The Elastic Limit is that unit stress at which the deformation of a p material begins to increase in a faster ratio than the applied loads. sometimes called the ELASTIC STRENGTH.

The Modulus of Elasticity or Coefficient of Elasticity. In tr on physics this is often called YOUNG'S MODULUS. It we take a bar of any material, say one inch square, of any length, and secured at one end, and other apply a force, say a certain number of pounds P, pulling in the di

* The ELASTIC LIMITS of materials must be considered in deciding upon worki stresses and in forming a judgment of the security of materials under stress. Wh elastic limit is considered the actual allowable unit stress is made a certain percen it, as 35 or 50%, according to varying conditions. Both ULTIMATE STRENGTHS an TIC LIMITS must be taken into account in practice. But the use of the FACTOR OF S as determined by the old method, is still a great help in the study and applica the principles of the mechanics of materials, and is used frequently in the Pocke

length, we shall find by careful measurement that the bar has been stretched ...ted by the action of the force. If we divide the TOTAL ELONGATION e, ...es, by the original length l of the bar, in inches, we shall have e/l, the ...NGATION ϵ, or the elongation of the bar per unit of length; and if we ... the unit stress S, developed (that is, in this case, the external force P, ...d by the area of the cross-section A, or P/A) by this ratio we shall have ...is known as the MODULUS OF ELASTICITY, E. Expressed in symbols and ...ations, $E = S/\epsilon = \dfrac{P/A}{e/l}$. Hence, we may define the MODULUS OF ELAS... ...as the ratio of the unit stress to the unit deformation. Another definition ... force which would elongate a bar of 1 sq in in cross-section to double its ...l length, if that could be done without exceeding the ELASTIC LIMIT ... material. This is evident from the above equation; for if $A = 1$ and ... E will equal P. These formulas apply only when the unit stress S or P/A ... than the ELASTIC LIMIT of the material. ϵ is an ABSTRACT NUMBER, ...e e and l are both linear quantities, and hence E is expressed in the same ...as S, that is, in POUNDS PER SQUARE INCH.

...an example of one method of determining the modulus of elasticity of any ...ial the following illustration is given:

...pose we have a bar of wrought iron, 2 in square and 10 ft long, securely ...ed at one end, and to the other end we apply a tensile force of 40 000 lb. ... force causes the bar to stretch, and by careful measurement we find the ...tion to be 0.0414 in. As the bar is 10 ft, or 120 in long, if we divide ...4 by 120, we shall have the elongation of the bar per unit of length. Per...ing this operation, we have as the result, 0.00034 in. As the bar is 2 in ..., the area of cross-section is 4 sq in, and hence the stress per square inch ...000 lb. Dividing 10 000 by 0.00034, we have, as the MODULUS OF ELAS...ITY of the bar, 29 400 000 lb per sq in. This is the method generally employed ...ermine the MODULUS OF ELASTICITY of iron ties; but E can also be deter...d from the DEFLECTION of beams, and it is in that way that its values for ... woods have been found. The modulus of elasticity is used in the deter...tion of the STIFFNESS of beams.

...e **Moment of a Force** with respect to an axis is the product obtained ...ltiplying the magnitude of the force by the shortest distance from the ... to its line of action. The shortest distance is called the LEVER-ARM of ...force. The moment of the force is the measure of the tendency of the force ...se ROTATION about the axis. (See Chapter VI and IX.)

...e **Center of Gravity** of a body is the point in the body through which ...ESULTANT of the forces exerted by gravity upon all the particles of the ... passes. A body may be balanced upon a point placed above or below ...center of gravity, because the RESULTANT of any number of forces may be ... in equilibrium by an equal and opposite force. Another definition of the ...ER OF GRAVITY of a body or bodies is: a point such that there is NO TEND...Y TO ROTATION about any axis drawn through it. (For center of gravity ...faces, lines and solids, see Chapter VI.)

2. Classification of the Principal Stresses Caused in Bodies by External Forces

...nsion is the stress that resists the tendency of two forces acting away from ...other to PULL APART two adjoining planes of a body.

...pression is the stress that resists the tendency of two forces acting toward ...ther to PUSH TOGETHER two adjoining planes of a body.

Shear is the stress that resists the tendency of two equal parallel f ing in opposite directions to cause two adjoining planes of a body to on the other.

Torsion is the stress that resists the tendency of forces to TWIST a

Combined Stresses. Parts of structures are often acted upon b external forces which develop stresses of different character, such as flexure and compression, flexure and tension, flexure and torsion, shear compression or tension, torsion and compression, etc.

CHAPTER II

FOUNDATIONS

By

DANIEL E. MORAN

MEMBER OF AMERICAN SOCIETY OF CIVIL ENGINEERS

1. Definition of the Word and Terms Used

finitions. The word FOUNDATION is derived from the Latin verb FUNDARE ing to establish or lay the base, bottom, keel or foundation of anything. English word is used in the broadest possible way to describe the base, ial or otherwise, on which anything is supported, and in technical language y be used to describe any part of a structure on which a subsequent oper- or construction is superimposed. Thus a plaster wall may be called the ATION for a fabric to be stretched thereon and the fabric in turn becomes OUNDATION for various coats of paint or other decorations. More specifi- ed in relation to a building or other complete structure the word FOUNDA- is unfortunately applied indiscriminately (1) to construction below grade, as footing courses, cellar walls, etc., forming the lower section of the struc- (2) to the natural material, the particular part of the earth's surface on h the construction rests; and (3) to special construction such as piling or used to transmit the loads of the building to firm substrata. In view of definite meaning of the word it is advisable to use it either to distinguish below grade, or below the tier of beams nearest to grade, from work above . In even a still more restricted sense, it might include only the work the cellar or basement-floor to rock or other solid foundation-bed. Chapter II, Subdivision 29, Chapter III, Subdivision 2, and Water- ing for Foundations, Part III.)

e Foundation-Bed. The natural material on which the construction s called the FOUNDATION-BED. Walls, piers and columns below grade lled, in general, FOUNDATION WALLS, PIERS AND COLUMNS to distinguish from similar construction above grade and occasionally those only the basement-floor are so called; the lower portions of walls, piers or ns which are spread to provide a safe base will be called FOOTING COURSES.

2. General Requirements

e Object of Foundations. The object to be borne in mind in designing undation is to provide a safe and permanent base for the superstructure that the movement of the base and of the superimposed structure shall be st possible and shall result in the least possible damage to the structure. ly meet the above requirements the design and construction should ful- e following conditions:

The Materials of Construction should be proof against all deteriorating ces, or, if any of the materials are liable to deterioration they should be ently protected.

Stresses and Future Changes. No part of the foundation-structure l, under any combination of loadings, be stressed beyond safe limits, and ibility of future additions or changes in the superstructure, or of a change use of the building, should be kept in mind.

(3) **The Load on the Natural Bed** should be kept within the safe limit f material, under the worst conditions to which it may be exposed. I this limit the amount of settlement allowable will in many cases detern limit rather than the safe ultimate bearing capacity.

(4) **Adjoining Excavations.** The possible danger to the structure o stability of the foundation-bed from adjoining excavations or other di causes should be guarded against as far as possible.

Physical Conditions of the Site. In order to meet the above requir the design should be suited to the physical conditions existing at the l The architect or engineer should personally examine the site. He shoul all available information relative thereto and, if necessary, should make and tests so as to secure reliable information on which to base his design foundation. The first step is, therefore, a detailed and exhaustive stud site to determine the characteristics of the foundation-bed on which th ture is to rest.

3. Geological Considerations

Character of the Foundation-Bed. A knowledge of geology is of assistance in many cases in making a proper estimate of the characte foundation-bed. While it is not proposed in the limits of this chapter to any general geological discussion the following notes may be of value in the architect to determine whether any given deposits can be relied affording a stable foundation-bed. Broadly speaking, as the location building may be in any part of the world, so the materials encounter belong to any one of the many geological formations forming the surfac earth. For practical purposes, however, the materials met with are divided into ROCK, or materials other than rock, roughly defined as EA

4. Composition and Classification of Rocks

Composition of Rocks. Rocks, and the earthy deposits derived fro are composed of various minerals of which many hundred kinds are each varying from the others in some particular of chemical compositio of crystallization or other characteristic. A rock or an earthy deposit m sist almost entirely of a single mineral, but it is usually composed of distinct minerals or of mixtures of minerals. The principal classes c forming minerals are:

(1) **The Silica Minerals**, composed of silica (SiO_2) in different forms;

(2) **Silicates** or combinations of silica, with various metallic bases;

(3) **Calcareous Minerals** composed of calcite or carbonate of lime (and its combinations.

(1) **Silica Minerals** are different forms of the oxide of silicon, kn SILICA. In the crystalline state silica is known as

Quartz. This is the most abundant of all minerals. Owing to its h and insolubility it resists decomposition and abrasion better than the with which it is associated and grains of it form the principal constit sandy deposits. In finely comminuted particles it forms a part of mos clays.

Flint, Chert, Agate, etc., are non-crystalline varieties of silica. SIL forms the cementing material in many sandstones and other rocks.

(2) **Silicates** or combinations of silica with various bases are second portance only to quartz.

...r, an important constituent of granite and other igneous rocks, is a ...of alumina with potash, soda or lime. When exposed to the action of ...it slowly decomposes, forming silicate of alumina, the base of clay. The ...position of granite results in the formation of clay and crystals of quartz ...ica. The mica is very slowly affected and the quartz is practically un...ed.

...a. The various mica minerals are silicates of alumina, with potash and ...constituents. All varieties are soft and split into thin elastic plates. ...particles of mica are frequently found in sand.

...blende and Augite are silicates of lime, magnesia, iron and alumina and ...frequent occurrence.

...ite, Talc and Soapstone Travertine are hydrated silicates formed from ...silicates by a chemical change in which a certain amount of water is ...bed. These minerals are soft and have a SOAPY FEEL. Special care should ...ken in building foundations on rock of this character to guard against any ...g on the foundation-bed or between parts of the foundation-bed.

... Calcareous Minerals. The following are the principal calcareous miner...

...ite ($CaCO_3$), carbonate of lime, when pure and crystallized, is known as ...ND SPAR. It is soluble in water containing CO_2. Calcite in varying de... of purity forms limestone and marbles. As a result of its solubility ...es and voids are frequently found in limestone.

...mite is a carbonate of lime and magnesia. It forms the so-called DOLO... LIMESTONES, which are less soluble than the calcite limestone.

...ite, Gypsum, Alabaster, Anhydrite, Aragonite and Apatite are other and ...portant lime-minerals.

...sification of Rocks. Rocks are classified not only according to the ...als of which they are composed, but also according to the way in which ...have been formed, as:

Igneous Rocks, which have solidified from a molten condition;

Sedimentary Rocks, which have been formed under water by mechani...ssure or by cementation due to chemical or organic proceesses;

Metamorphic or Plutonic Rocks, which have changed from their original ...cter as igneous or sedimentary rocks.

Igneous or Plutonic Rocks are not truly stratified. They may be ...lar, crystalline or glassy in texture. GRANITE, SYENITE, BASALT, TRAP, etc., ...amples. LAVA, PUMICE and OBSIDIAN are volcanic products, as are also ...e deposits of mud and ash. With the exception of volcanic ash and mud, ...neous rocks are enduring and are not liable to present any unforeseen weak...s in foundation-beds.

Sedimentary Rocks are composed of sand, clay and other materials ...ng from the breaking down of the original igneous rocks. These materials ...eposited in horizontal beds generally by settling from water, and the con...ion into rock was generally affected under water by chemical, mechanical ...nic action. The resultant rock-masses are stratified as a result of their ...ent materials having been deposited in layers. As sand and clay are ...st abundant products of rock-decomposition, so the sedimentary rocks ...st frequently SILICEOUS (sandy) or ARGILLACEOUS (clayey).

...stone is composed of grains of sand cemented together by silica, oxides ... or carbonate of lime. The durability of sandstone depends on the solu...

bility of the cementing material. Carbonate of lime being soluble, sand containing it as cementing material yield to the weather and are not so as sandstones having silica or iron oxide as cementing material.

Argillaceous Rocks contain clay with fine sand, mud, etc., and while SHA some other varieties are compact and hard when first uncovered, they ar to deterioration when exposed to frost, water and other disintegrating ag

Limestone is composed more or less of carbonate of lime derived fr calcareous skeletons of marine animal and vegetable organisms. The acter of limestone varies greatly. In so-called FOSSILIFEROUS LIMES fossils of shells or corals indicate clearly its origin, but in other limestone are no fossils or other indications of the organic origin of the calcareous m Admixtures of sand, clay, or other impurities may make it difficult to dist certain limestones from sandstones or shales.

Dolomite is a limestone containing a high percentage of magnesia.

Hydraulic Limestone is a limestone containing clay.

Chalk is a soft limestone composed of the fine shells of minute marine isms. In general, the purer the limestone the more soluble it is and the the danger from fissures or caverns due to the action of water.

(3) **Metamorphic or Plutonic Rocks** are rocks which have been from sedimentary or igneous rocks by heat, compression, or moisture, alone or in combination. Thus by heat from a nearby intrusion of molte limestone is changed into a crystalline marble. The general effect of MORPHISM is to produce a hard or durable rock.

Quartzite, a metamorphosed sandstone, is a crystalline rock of great h and durability.

Slate is a hard dense rock, sometimes with a well-defined tendency to s thin plates. It has been formed by metamorphic action from clayey sha is generally durable, but liable to slide along planes which are sometim allel to the cleavage, or along seams which are not parallel to the cleavag

Gneiss is a "laminated metamorphic rock that usually corresponds alogically to some one of the plutonic types." * There are many varieti classified in accordance with the igneous rocks to which they most nearly spond in composition. Some varieties resemble granite, but the lamin striped aspect is generally characteristic. They are generally compa durable.

Schists are similar to gneiss but are more finely foliated or striped. I SCHIST there are layers or foliations composed of fine grains or plates c Mica-schists are liable to decomposition and it frequently happens that tions have to be carried to great depths through decomposed rock of th acter before solid rock is encountered. The material resulting from the position of this rock contains fine grains of mica and other fine mater when wet, acts as QUICKSAND.

Rock as a Foundation. All rock, if sound and not liable to slip proverbially a solid foundation and capable of supporting any weight building is likely to impose on it. Care should be taken that rock l disintegration is protected from the weather, water-action, or other disi ing influences.

5. Geology of Earthy Material

Earth and Soil. Materials other than rock, resulting from the dis tion of rock-masses, are broadly classed as EARTH. The word SOIL, wh

* Kemp.

...gnate any earthy material not rock, is a misnomer, in that the idea of ...ty, or the lack of it, is conveyed when the word SOIL is used.

...he agencies producing the disintegration of the rock masses which form or ...ke the entire surface of the earth, are various, but for the purpose of this ...er they may be defined as (1) CHEMICAL and (2) MECHANICAL.

...Chemical Agencies. By CHEMICAL ACTION OR DECOMPOSITION, a rock ...of great strength and hardness and of complicated mineralogical structure ...disintegrate into a noncoherent mass of elementary minerals. Thus a ...thic granite under the combined action of water and varying temperature ...egrates, the crystals of feldspar changing chemically and forming the ...ted silicate of aluminum known as CLAY, while the crystals of quartz, ...or hornblende, being more resistant to chemical action, retain their chem... ...identity but become detached particles of SAND.

...Mechanical Agencies. By the MECHANICAL AGENCIES, such as the action ...st, moving water or ice, fragments of rock are detached from the ledge of ...h they originally formed part and are subsequently transported, by the ... of glaciers or streams, or by the wave-action in bodies of water. The ...ion between the materials thus roughly thrown about breaks up the rock-...es into smaller and smaller pieces without altering the composition of the ...material.

...ving Water. As flowing water more readily transports small particles ...large ones, the larger pieces of rock move intermittently during periods of ...or flood and are deposited as soon as the velocity of the water falls; while ...maller particles are held in suspension longer and, as the velocity of the ... falls, are deposited in the order of their size, the largest first. The ...upper courses of streams and rivers in mountainous regions constantly roll ...ind together the materials in their rocky beds, the heavy masses being ... slowly. The attrition between the fragments forms GRAVEL and SAND ... are washed down stream to be deposited, as the current slackens, first as ... of GRAVEL, then as SAND-BARS, and finally, in the slow-moving lower ... as BEDS OF SILT and ALLUVIUM.

...ciers and Glacial Deposits. The action of glaciers is similar to the ac-... of streams. Glacial deposits, the so-called GLACIAL DRIFTS, are composed ...d clay, gravel and boulders but, in general, there is a noticeable differ-... between glacial deposits and deposits made by rivers or streams. In glacial ...its the boulders frequently exhibit groovings or scratches on their faces ... the edges and surfaces of the boulders are generally sharp, so that a ...er may appear as if it had been recently fractured. They rarely exhibit ...ooth, water-worn and rounded surfaces found on boulders formed by ...action. Moreover, the glacial boulders may be found singly, or unas-...ed with other boulders in a deposit of sand or gravel. The deposit differs ... river-deposit in that there is no classification as to size; the boulders may ... on the surface or may be disseminated as if by accident through the sand ...avel forming the body of the deposit. Such glacial deposits partake of ...racter of a rough artificial fill without the stratification or classification ...ze which is characteristic of river-deposits. In glacial moraines or dump-...ounds it not infrequently happens that the surface-water finds underground ...s forming so-called SINK-HOLES. A line of glacial deposits extends across ...tinent of North America from Long Island westward. The southern ...an be determined by reference to geological maps.

...ial and River-Deposits Distinguished. It is important to distinguish ... GLACIAL and RIVER-DEPOSITS, because, while the occurrence of glacial ...s gives, in general, little or no information as to the character and value

of the surrounding deposits, the occurrence of boulders, on the other h river-deposits is generally an indication that the bed of which they form has been thoroughly consolidated as a result of the river-action which fon and, also, because such deposits generally extend down to rock or to som pact material which at the time the deposit was made was capable of r the action of rapidly flowing water.

Wave-Action on Lakes and Along Coast-Lines is constantly worl the materials composing the beach. Rock-masses are broken away fro and ground together, producing boulders, gravel and sand. The sand carried more readily by the tidal currents, is deposited in the more shelter tions and forms BEACHES, while the larger rock-masses remain near th of origin in BARS and REEFS.

Beds of Sand, Gravel and Boulders deposited by the action of w the SHORES OF SEAS OR LAKES are not necessarily constant in character a should be made to determine the character of the material underlyi BEACH-FORMATIONS. In large river-valleys where the general forma composed of silt or other fine material little reliance should be placed occurrence of BEDS OF GRAVEL, even if such beds extend over large areas. should be made to determine that such beds are not underlain by les worthy materials. Where tributary streams discharge into large valle may deposit BARS OF SAND, GRAVEL and BOULDERS on top of the silt, other materials formerly deposited by the main river. (See page 136 general topographical conditions should serve as an indication of danger cases.

Results of Chemical and Mechanical Action. As a result of t going brief description of the agencies at work it may be seen that IC and STREAM-ACTION alike tend to disrupt rock-masses and to produce b gravel, sand and finer materials. The ultimate result of the combin CHEMICAL ACTION and MECHANICAL ACTION is to reduce the hardest rock finest sand, the most impalpable clays, silts and muds; and the ACTION C WAVE and MOVING WATER is to classify such materials in deposits of g uniform size.

6. Materials Composing Foundation-Beds

Classification and Definitions. The following list includes the r which are most frequently encountered, with their definitions.

Rock (solid rock, bed-rock, or ledge). Undisturbed rock-masses for undisturbed part of the original rock-formation.

Decayed Rock (rotten rock). Sand, clays and other materials from the disintegration of rock-masses, lacking the coherent quali occupying the space formerly occupied by the original rock.

Loose Rock. Rock-masses detached from the ledge of which they o formed a part.

Boulders. Detached rock-masses larger than gravel, generally roun worn as a result of having been transported by water or ice a consider tance from the ledges of which they originally formed a part.

Gravel. Detached rock-particles, generally water-worn, rounded a mediate in size between sand-particles and boulders.

Sand. Non-coherent rock-particles smaller than ¼ in in maximum sion.

The material resulting from the decomposition and hydration of feld-rocks, being hydrated silicate of alumina, generally mixed with powdered quartz and other materals.

Hard-Pan. Any strongly coherent mixture of clay or other cementing with sand, gravel, or boulders.

A finely divided earthy material deposited from running water.

Finely divided earthy material generally containing vegetable matter deposited from still or slowly moving water.

Loosely used to describe any earthy material.

Earthy material capable of supporting vegetable life and generally to material containing decayed vegetable or animal matter.

Earthy material containing a large proportion of humus or vegetable

Earthy material containing a proportion of vegetable matter.

Compressed and partially carbonized vegetable matter.

7. Characteristics of the Materials of Foundation-Beds

Rock, or, as it is locally known, BED-ROCK, or LEDGE, is proverbially foundation. The harder rocks, such as granite, trap, slate, sandstone, etc., are all capable of carrying the load of any ordinary structure. rocks, among which may be classed the shales, shaley slates and marley limestones and clay stones, should not be loaded with more than per sq ft unless they are tested for greater loads. In all cases where are to be placed on what is supposed to be solid rock, care should be to determine whether or not the supposed solid consists of a detached and, also, in case the bedding-planes of the rock are inclined, if there is from a slip of the layer forming the foundation-bed. (See pages 139 and to side-slope locations.)

Decayed Rock. Certain igneous or metamorphic rocks such as granites, etc., frequently disintegrate, forming so-called ROTTEN ROCK or DECAYED The decayed rock is generally found in conformity with the ledge of it originally formed a part. It may retain the stratification, color and of the solid rock, but as a result of the disintegrating effect of water agents, it has lost the solid character of the original rock. When with a hammer it does not give the characteristic ringing sound of solid It may be fairly compact and hard, or so soft as to be readily excavated pick and shovel. The amount of such disintegrated rock overlying the rock varies greatly; in some cases the removal of a few inches will disclose rock, in other cases the layer of decayed rock may be many feet in thick-Test-borings in rotten rock give samples similar to the samples from solid so that it frequently happens that while the foundations are planned for the excavations disclose a thick layer of rotten rock. In such cases, impracticable to carry the footings down to solid rock, it may be necessary the size of the footings or to adopt some other expedient.

Rock. Where a rock-mass detached from the ledge of which it orig-formed a part is encountered it must not be loaded in excess of the safe of the material by which it is surrounded. If the voids between ad-pieces of loose rock are completely filled in with hard-pan, compact or clay, the loading may be the same as for the filling-in material. should be taken to determine that no voids exist. In natural rock-

fills, as in artificial rock-fills, it may happen that large voids exist betw rock-masses, forming passageways for streams of water, in which case t extreme danger of settlements.

Boulders, Gravel and Sand. Boulders are rock-masses which hav transported by water or ice-action. Boulders are sometimes found di ated through sand and clay and in such cases the load should be limited safe load of the material in which they are found. At other times bould found in beds, packed closely together, with the interstices filled in with sand, or clay. In such cases it is usually safe to assume that no furth solidation of the mass is likely to take place. If the bed of boulders ext rock, they will safely sustain any load which will not crush them.

Gravel. The name GRAVEL is given to rock-particles larger than sa smaller than the rock-masses known as BOULDERS. If compact, an underlying bed of poorer material exists, gravel forms a most desirable tion-bed, equal to sand or boulders in supporting power and not as l be disturbed by adjoining excavations or pumping operations. If ce it may partake of the quality of hard-pan or rock. Care, however, sh taken to determine whether or not the bed of gravel has been deposited layer of silt or quicksand. It is possible for this dangerous condition t (See page 134.)

Sand. Sand is composed of comminuted rock-material. As quart most abundant rock-mineral and as its hardness and insolubility make i resistant to disintegrating action, it will be found to be the principal con of most deposits of sand or sandy material. Grains of mica, feldspar and other minerals are frequently found. Sand is described as bein MEDIUM, or COARSE, according to the size of the grains of which it is co

Coarse Sand may contain particles of gravel, but after elimina particles which will not pass a screen with 4 meshes to the inch it will l that a large proportion of the remaining material is too coarse to pass a sieve.

Fine Sand, on the other hand, may contain no particles which will a 20-mesh sieve, and a considerable proportion which will pass a 100-me

Very Fine Sand is frequently mistaken for clay and, indeed, genera contain some clay, as clay generally contains fine sand.

Uniform Sand is sand in which there is relatively a small variatio size of the particles.

Balanced Sand is sand in which the size of the particles varies from small and in which there is no great difference in the numbers of pa each size.

Clean Sand contains no clay or loam, but a pure sand containing a l centage of fine particles is often considered to be NOT CLEAN.

Sharp Sand is clean sand containing coarse, angular grains. Whe grasped in the hand it gives a NOTE, due to the particles slipping over ea Sharp sand is generally esteemed for use in mortar, although it requi cement to fill the voids and, in the writer's opinion, is not as desirable as rounded sand.

Rounded or Buckshot Sand is composed of rounded grains not c together.

Quicksand. This term is popularly used to describe any fine sand, ture of fine sand and clay, which, when wet, forms a soft, unstable

popular mind quicksand is supposed to have some mysterious and peculiar properties which result in a tendency to FLOW LIKE WATER and to SUCK IN animate and inanimate objects. These manifestations are connected with various theories as to the composition of quicksand, some persons insisting that quicksand must contain flakes of mica or some slippery mineral, others that the particles must be extremely fine or spherical in shape, while others contend that there must be a certain proportion of fine clay with the sand. The fact is that any uncemented sand, when subjected to the action of moving water, will move and that any sand moving as the result of the action of water becomes quicksand. The finer the sand the more readily it is affected by a current of water, so that fine sands are more troublesome than coarse sands. A coarse sand having large voids, permits the flow of a certain amount of water through it; if this flow has not sufficient velocity to disturb the particles of the sand, the sand can be drained without moving it. In a fine sand, having very small voids, a similar flow of water will cause the whole mass to move and there is great difficulty in draining it without producing a current sufficient to cause it to move or flow.

Excavations in Quicksand are made difficult by the tendency of the sand forming the sides of the excavation to flow into the excavation; and even if the sides of the excavation are protected, it not infrequently happens that the bottom of the excavation will LIFT, that is, there will be a movement of material from points outside of the line into the excavation, the movement in general following a curved line, and carrying the sand, under the protected side walls of the excavation. In such cases some advantage may be gained by surrounding the excavation with driven wells and draining the soil by continued pumping through sand; in other cases, wooden or steel sheeting may be driven to a point below the depth to which the excavation is to be carried, or to some underlying layer of impervious material, in which case the sheeting will act as a coffer-dam to cut off the flow of material. Such sheeting, however, must be practically water-tight, as extremely fine sand, when in the condition of quicksand, will flow through very small apertures.

Quicksand as a Foundation-Bed is objectionable on account of the danger of its moving or flowing, in case it finds any outlet such as would be afforded by an adjoining excavation. Cases are known where excavations have permitted the escape of quicksand and resulted in the settlement of buildings at a very considerable distance. Such settlements have occurred not only when the footings themselves rested on quicksand, but also when they were on a stratum of coarse sand, gravel or clay of good quality which rested on an underlying stratum of quicksand.

Pockets of Quicksand. It frequently happens that pockets of fine sand are found in deposits of mixed character. Where such pockets are small in extent the fine sand may be removed and the spaces filled with concrete. Where the pockets are larger it may be necessary to carry piers through them to a better foundation-bed, to drive piles, or to resort to other expedients.

Fine Dry Sand is readily converted into quicksand by the addition of water, and this fact should be carefully borne in mind in considering the load on fine sand, as a material which in dry weather is apparently safe, may be, in wet weather, an extremely dangerous one. It is frequently stated that confined quicksand is a perfectly reliable material on which to found a building. While this, as a theory, cannot be controverted, it is a dangerous assumption to act on because of the impossibility of providing that the fine sand shall be always confined.

Variation in the Size of Grains of Sand. The accompanying diagram (Fig. 1) shows graphically the results of sieve-tests on characteristic sands.

The dash-line curve (1) is an average, giving the results of sieve-tests on so-called quicksands; the full-line curve (2) gives the result of sieve-tes natural sand which would be classed as a good building sand; the dot-an curve (3) gives the result of sieve-tests on a fine beach sand remarkable

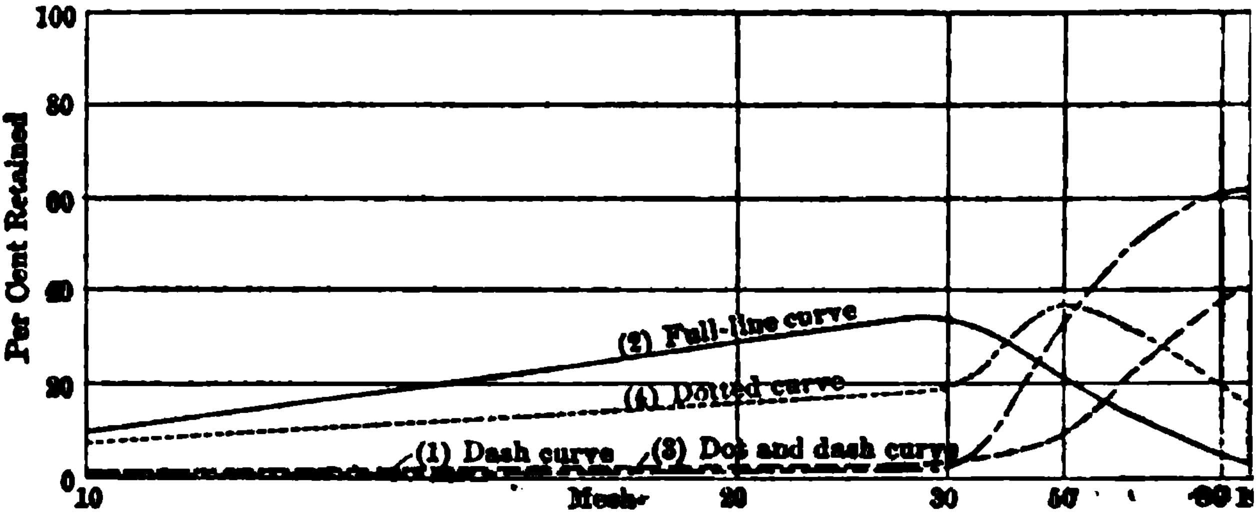

Fig. 1. Graphical Illustration of Results of Sieve-tests on Sands

uniformity of the size of its grains. For purposes of comparison and i to show the variation in sands which appear to be substantially the sa dotted curve (4) has been added. This shows the result of tests on a ban apparently as coarse as sand (2), but containing a much larger percent fine particles between 0.015 and 0.0055 in in diameter. Fine sand freq contains a considerable proportion of clay. A chemical analysis of a so QUICKSAND from the down-town section of New York City, reported on writer by Dr. C. F. McKenna, is as follows:

Mark: "Commercial Cable"

Silica	73.76
Alumina and oxide of iron	18.52
Lime	1.60
Magnesia	1.48
Loss on ignition	2.26

A rational analysis shows the following composition:

Quartz, as given	39.38
Clay and mica, as given	23.94
Feldspathic detritus	36.68

On the other hand, a sample of extremely fine sand from Michigan, of 75% passed a 200-mesh sieve, appears to be absolutely pure quartz.

Clay. When pure, clay consists of hydrated silica of alumina, the p of decomposition of feldspar. Ordinarily, various impurities are mixed w clay, so that, in general, clay may be considered a mixture of hydrated of alumina with other finely divided minerals. Mixtures of clay and sa found, varying from beds of nearly pure clay to beds of nearly pure san no definite classification can be made.

The Effect of Moisture on Clay. Clay as generally found in excav is in a plastic condition due to the presence of moisture, the amount of present varying greatly. On drying, the clay shrinks in volume and lo plasticity, becoming a firm and coherent mass resembling in consistency dried brick. Large masses of clay are liable to crack into a number of

...ents during the process of drying, as the result of the shrinkage in volume. ...n these lumps are crushed or ground the clay becomes an extremely fine ...palpable powder. The loss in volume due to the change in the condition ...the clay from a moist, plastic state to a thoroughly air-dried condition may ...ount to from 10% to 20% of the original volume. Compact, moist clay is ...rvious to water in the sense that water cannot pass through it as it would ...ugh porous sand; but when clay is exposed to water the clay gradually ...rbs the water, so that eventually the entire mass becomes saturated and ...ened by the water.

...lay as a Foundation-Bed. Clay is not a reliable material on which to ...d a building; first, because of the PLASTICITY of the clay when wet, and ...dly, because of its TENDENCY TO SHRINK on losing its contained moisture. ...e plasticity of clay increases with the percentage of contained water, so that ...n, hard clay may be converted into a liquid puddle by being agitated in the ...ence of a sufficient amount of water. The plasticity is also increased by ...sure, as is shown by the action of clay in a brick-machine. Clay, in a founda...-bed under moderate pressure imposed on it by the footings of a structure, ...uently develops this QUALITY OF PLASTICITY, the clay moving out from be...th the footing and causing serious settlements and displacements of the ...ings. This movement of the clay may be a local movement, as referred to ...h footing, in which case the clay flows from beneath the footing laterally ...ard the side and then upward, causing the surface of the adjacent ma...al to rise and to form so-called BULGES or WAVES. If this motion is uniform ...m the center toward the sides, the footing may settle vertically, but more ...erally the movement will not be symmetrical and the footing will settle ...re on one side than on the other. Such movements of the clay may be re...ed or prevented in some cases by the simple device of loading the surround... soil, as, for example, by a concrete floor.

...ovements of Clay Foundation-Beds. The movement of the clay may ...e a larger scale, amounting to a general flow of the clay underlying the ...ire building toward some point where the pressure on the clay is less than ...e pressure resulting from the load of the building. Such general movements ...e more likely to happen if the building is located on the side of a hill, so that ...e clay finds some outlet at a point below the level of the footings. It fre...ently happens that adjoining excavations cause settlements to buildings at a ...siderable distance, by affording an outlet to a bed of clay. As noted else...ere (pages 135 and 146), beds of clay resting on inclined strata of rock or ...er material are liable to move downward, sometimes with a slow, almost ...perceptible movement, and at other times forming landslides of greater or ...s magnitude.

...otection of Clay Foundation-Beds. Where the foundation-bed is clay ...ed with a considerable amount of clay, it is advisable to protect it from ...er-action, so far as is possible, by a system of drains surrounding the site ...the building and by diverting the surface-water from the building. Care ...ld be taken in back-filling around exterior walls to prevent any accumula...n of water which might affect the material under the footing. The neglect ...such precaution has frequently resulted in serious settlements during, or ...ediately after, construction.

...d, Silt, Peat and Other Unstable Materials. When the site of a ...ture is in a marsh or on materials which are not capable of affording a ...foundation, the only alternative is to resort to the use of wooden piles, ...ete piles, or piers sunk to an underlying and firmer strata. Such special

constructions will be described under Subdivisions 27, 28 and 29, which cc wooden piles, concrete piles and piers sunk by the coffer-dam or c methods.

Filled Ground. All artificial fills and some natural fills are liable to a or less uniform but continuous settlement or shrinkage due to the gradua solidation of the material of which the fill is composed. Where the fill is o rock this consolidation may amount to little, but where the fill is of eartl especially where it is of mixed materials, the shrinkage will not only be la amount but will continue for a very long period. For example, wher has been thrown on top of a rock-fill each rain-storm will wash some of th into the voids in the rock-fill, and this action will be continuous until the voids are filled in. Any vegetable matter, or other matter liable to and shrinkage in volume, will increase the total shrinkage of the mass. tain natural deposits, such as beds of peat or soils containing vegetable m are apt to shrink in volume from the same causes. When it is necessa found a building on such material it is inevitable that the footings will with the mass, notwithstanding that the unit load on the foundation-bed small as to be negligible. In such cases the settlements may be vertica uniform; but if the depth of the fill under one part of the building is gr than the depth under another part, the settlements will not be uniform, a shrinkage in the fill will, in general, be in proportion to the depth of th No important building should be founded on such material and, whe possible, the footings should be carried down through the filled-in mater some more reliable underlying stratum.

8. Allowable Loads on Materials of Foundation-Beds

General Considerations. Owing to the infinite number of variations i materials encountered and the conditions affecting the reliability of such ı rials, no general or definite rule can be given, and every case should be care investigated before determining the allowable unit load on the foundation If the material and conditions are uniform over the entire site of the bui a uniform unit load may be used, but in practice it is frequently found entirely different conditions exist under different portions of the same bui and in such cases great care must be exercised in determining the unit l For instance, one section of a building may rest on rock and another sectic a light compressible soil or on a clay of doubtful stability. In such case unit load on the compressible soil or on the clay must be reduced as muc possible so as to reduce the differences in settlements between the two sec of the building to a minimum. If the entire building were on a compres soil a very considerable settlement might be allowable, provided it was unif but in this particular case it is known beforehand that the part of the buil on rock will not settle at all and that any settlements of other parts of building must be considered as unequal settlements, and, as such, liable to duce cracks and distortions in the building. It is also important to remea that a certain unit load on compressible soil may be safe, in that the soil ultimately safely support that load; but the use of that load would neverth be inadvisable on account of the excessive settlements. In this connectic may be said that a considerable settlement, if uniform, in a detached buil may be a matter of no importance; but that where a building is to be structed in contact with adjoining buildings or where additions are to be n to an existing building, the total amount of settlement becomes a matt prime importance. These and other considerations, such as the characte

posed building and of the material composing it, should be borne in in selecting the unit load for any given foundation-bed, irrespective of the pressure as given by building codes or by examples quoted in this chapter.

Loads on Rock. The safe unit load on rock may often amount to than the crushing strength of brickwork or stone masonry, and in nearly any material worthy of the name of rock is capable of supporting from 30 tons per sq ft.

Loads on Sand, Gravel and Boulders. When compact and con-terally these materials are capable of supporting 10 tons per sq ft with-ppreciable settlement. It rarely happens, however, that it is advisable to such materials with more than 5 tons per square foot.

Loads on Loose Sand. By loose sand is meant sand which has been thoroughly compacted and which may settle by its own weight inde-ntly of a superimposed load. All such materials should be tested and unit load reduced in accordance with the result of such tests.

ds on Fine Sand or Quicksand. It is probable that fine sand, if tely confined, will sustain as heavy a load as coarse sand, but in view of fact that if afforded the slightest opportunity it is liable to lateral displace-t, it is inadvisable to found any structure on such material. When it is ative to place the footings on such material the unit load should be reduced ch as possible and preferably to less than 2 tons per sq ft, and great care ld be taken to connect all footings with a continuous layer of concrete so to prevent any flow of material into the cellar-excavation. Care should taken, also, that any sumps, pump-pits, drainage-arrangements and sewer-ections for the building do not permit the escape of any quicksand..

Loads on Hard-pan and certain cemented sands partaking of the e of hard-pan may approximate rock in hardness and reliability. Such rials, however, are liable to soften if exposed to water. If these materials, uncovered, are dry, experiments should be made to determine how they e when wet, and if the level of the water in the ground is liable to change to reach the layer of hard-pan, the load should be correspondingly reduced. ented hard-pan containing gravel has been frequently loaded with more 10 tons per sq ft. Care should be taken, however, to determine that layer of hard-pan is continuous to a solid substratum, as it frequently happens layers of hard-pan and fine sand or clay are deposited alternately.

fe Loads on Clay. Ordinary clay should not be loaded with more than ns per sq ft. If soft and plastic, a load of 2 tons per sq ft may produce visible settlements. Clay with so large a percentage of sand that it loses plasticity has been loaded with from 4 to 6 tons per sq ft without undue lements, and sand or gravel containing sufficient clay to act as a cementing rial will partake of the qualities of hard-pan. In general, however, clay e most dangerous of all the materials on which structures are founded and unit load should be reduced to a minimum and every precaution taken to ent the flow of material. Undue reliance should not be placed upon load-tests of clayey soils. It is probable that a loading on a large area which produce a movement of the clay will on a small area have no effect, so that unsafe to rely upon the results of a test-load applied to an area smaller than actual supporting areas to be used. From the experience gained in the struction of large buildings in Chicago which were FLOATED on clay, the wable unit load has been generally reduced to 2 tons per sq ft and, in writer's experience, a load of less than 2 tons per sq ft on clay has pro-d settlements varying from nothing to 12 in.

9. Unit Loads on Foundation-Beds Allowed by Building Co

Variations in Building Codes. Table I gives an outline of the requi of different cities as to the allowable unit loads on different mater contained in their respective BUILDING CODES OF REGULATIONS. Wh allowed loads given may in some cases be based upon actual experience respective localities, it is more likely that they are based upon the ind experience of the authors of the codes, or are copied from other codes architect should, therefore, not place too much reliance on the unit loads by the codes, but should investigate each case and determine for him proper allowance to be made.

Special Requirements of Some Building Codes.* The Boston co vides that "the footing shall not overload the material on which it rests

The New Orleans code limits the maximum load to 1 400 lb per sq ft, th city being on an alluvial-delta formation.

The Buffalo code limits the load on SOIL to 3¼ tons per sq ft; if the SOIL than hard clay or gravel the supporting areas "shall be extended as dir

The Cincinnati code limits the load on soils INFERIOR to those listed, t per sq ft.

10. Investigation of the Site

General Considerations. To determine the character of the material will be encountered at the level of a foundation-bed, the architect shou get as definite information as possible from others as to their experience i ing excavations and erecting buildings in that vicinity. In some localit subsoil conditions are uniform over large areas, while in other localities tant variations may occur within the limits of a city lot. Abrupt cha surface-topography, changes in the character of the surface-soil or in the vegetation, proximity to old or existing water-courses are suggestive surface irregularities. In such cases, and in all cases where there is any as to subsurface conditions, a sufficient number of exploratory borings pits should be made to determine the facts. This exploratory work sh below the level of the proposed footings, should determine the ground level and insure that no unsuspected layer of quicksand or other uns material underlies the foundation-bed. The methods in use for such e tions are as follows:

Testing in an Open Pit. For shallow work an open pit is the mo isfactory method as it allows actual inspection of the undisturbed material considerable area. If the excavation is in firm material, no sheet-piling o protection may be required; but if in flowing material, or if carried than adjoining footings, timber sheeting or steel sheeting should be em If the excavation is carried no deeper than the proposed footing-level, the lying material should be tested by one of the methods hereinafter describ

Testing with Steel Bars. A steel bar with a pointed end or a ste provided with a steel point is driven to the required depth by a maul o falling weight. While no samples can be obtained by this crude met may determine the ground-water level, and a little practice will enable distinguish sandy from clayey soils by the sound given out when the twisted. The difficulty of driving is a rough index of the degree of the pressibility of the soil. It should be remembered, however, that an material will afford considerable resistance to the bar and that a small b will stop it; so that not much reliance can be placed on a report that th DROVE HARD or that it REACHED ROCK.

* As codes change, quotations must be verified.

Testing with Post-Hole Diggers. For shallow explorations in easi cavated material, the ordinary post-hole digger used for fence-posts, c longer and larger ones used for telegraph-poles, can be used to depths of 6 to 8 ft.

Testing with Augers. In clay or similar material a single or double carpenter's auger welded to a long rod, or the so-called POD-AUGER maj satisfactory samples. In gravel or loose and sandy material, the sides c hole fall in, clogging the operation and destroying the samples.

Testing by Dry-Pipe Borings. A POD-AUGER or the above-desc CARPENTER'S AUGER can be used inside a casing-pipe. The pipe shou driven so as to keep close to the bottom of the hole made by the auger. pipe prevents the material falling from the sides of the hole and the aug cavates and loosens the material ahead of the pipe and facilitates driving. above methods are not generally successful for deep holes or where g boulders or compact material interferes with driving the pipe.

Testing with Wash-Pipes. For test-borings over 10 ft in depth the m in most frequent use is the WASH-PIPE METHOD. In this method a wrough or steel pipe known as the CASING-PIPE or DRIVE-PIPE is driven into the ea much the same way as in the DRY-PIPE METHOD, but the driving of the p facilitated by the use of a JET OF WATER. The lower end of the casing-p provided with a hollow SHOE or reinforcement, slightly larger in outside dia than the casing. This serves to protect the pipe from injury in driving th gravel or hard-pan, and forms a hole slightly larger than the diameter c casing. The upper end of the drive-pipe is protected from injury by an an drive-head which has a threaded part fitting the thread on the casing-pip a central hole to admit the jet-pipe. The jet-pipe is small enough to p it to freely enter the casing-pipe. The lower end is contracted so as to pr a jet-action. The upper end is connected with a water-supply which mu under considerable pressure. The driving-mechanism consists of a cas weight with a central vertical hole large enough to admit the wash-pipe stationary verticals supporting a BLOCK-AND-FALL and an arrangement releases the weight when it has reached a predetermined height. With arrangement, water is continuously pumped through the jet-pipe, the leng which is regulated so that the jet-action loosens the material immediately l or AHEAD of the casing. Some of the jetting water returns to the surface side of the casing and thus lubricates the surface in contact with the ou material. Another part of the water returns to the surface in the an space between the wash-pipe and the casing, carrying with it particles o material loosened by the jet. As the jet loosens and washes away the ma immediately below the casing, the latter is driven deeper by repeated blo the ram, the driving and washing being carried on at the same time. operation is thus continuous until the top of the casing comes close to the face of the ground, when the hammer drive-head and hose-connection a moved to permit additional lengths of pipe to be added to the casing and w pipes, after which the hose-connection, drive-head and hammer are rep and the operation is resumed.

Borings can be made by this method to great depths in sand, clay or suitable material. Samples of the material encountered are obtained by s ment from the water returning between the jet-pipe and wash-pipe. T samples are not accurate samples as the water separates the materials. finer particles do not settle readily and the large and heavy particles may be brought up at all. It is evident that such samples do not give any i as to the solidity of the original deposits. If large gravel, hard-pan or bou

...ountered there will be great difficulty in forcing the casing past such ...tions. In such cases a DRILL-ROD is sometimes substituted for the JET ... obstruction broken up into small pieces or pushed to one side; but in ... case it is difficult to get any sample or real indication of the character ... obstruction. If solid rock or large boulders are encountered, no further ... can be made with the casing and no sample can be obtained by this ... Resort must then be had to one of the CORE-BORING METHODS described ..., to determine the character of the obstruction encountered.

...ing by Core-Borings. These borings can be made through rock or ... and accurate samples obtained. In all core-boring methods the hole ... by rotating a pipe-like tool which makes an annular cut in the rock ... a cylindrical core which is afterwards detached and brought to the ... by a gripping-tool called the CORE-LIFTER. The cutting is done in ... ways.

...mond Bits are annular rings fitted on the lower end of the hollow pipe ... the rotating drill-rod and furnished with a number of small diamonds ... so as to form cutting-edges, which, when rotated in contact with the ... gradually wear away the required annular space. The diamonds employed ... as BORT, BLACK DIAMONDS, or CARBONS, and their only resemblance ... stones used by jewelers is the necessary hardness. The carbons are ... secured in a soft metal bed, in sockets drilled in the bit, and they pro... ... the bit and also sufficiently inside and outside to insure the cutting ... large enough to provide clearance for the bit and the attached drill ... pipe.

...t-Drills. The same result is arrived at by the SHOT-DRILL METHOD, by ... particles of chilled cast iron called SHOT are used as the abrasive or cutting-... The shot is poured loose into the hole and forced against the rock by ... bit.

...ciency of Drill-Methods. Both of the drill-methods mentioned are ex... but as they are the only methods which will give an accurate sample ..., one or the other must be employed where the accurate determination ... is necessary. If the core corresponds to the known underlying rock-... and the rock is continuous for a length of from 8 to 20 ft, it is safe ... that solid rock has been reached. If, however, the core is of differ... ... from the known underlying formation, the probability is that a boulder ... encountered. If the core is not continuous it may indicate that ... seams in the rock or that there are detached rock-masses. The above-... methods are used after the overlying earth has been penetrated by ... the PIPE-SINKING METHODS previously described.

... Results of Pipe-Borings are frequently misleading and misinterpreted, ... care should be taken to compare the samples with samples obtained ... other borings where the exact character of the materials tested is known.

11. Loading-Tests

...eral Considerations. Loading-tests of the materials forming the foun-... ... are made to assist in determining its safe bearing capacity. It is not ... to what extent the supporting power of a given soil varies with the area ... to the unit load, and tests on small areas are not a safe guide for the ... on large areas. On account of the expense involved, tests on large ... rarely made, the usual test being on an area of about 1 sq ft. The ... be made on an undisturbed portion of the foundation-bed, leveled ... the test-load, and for a space around the area tested, so that the

adjoining material is not reinforced or SURCHARGED by a bank of unex
material. The load should be applied with the least possible jar or mo
of the surface in contact with the material of the foundation-bed.

Explanation of Methods. A convenient arrangement for this consists of a vertical timber or post carrying a platform to receive the te and having four horizontal guys at the top to keep the post in a vertical p The bottom of the post, forming the loading-area should be approximatel 12 in and its exact area should be known. The platform, sufficiently to support the load to be applied, should be concentric with the post close to the bottom of the post as practicable. The load may be pig iron, or sand in bags, or any other convenient material. The guys should be than four in number, should be attached to the top of the post and sho horizontally so as not to pull up or down on it. Levels should be re point on the post above or below the load, as may be most convenien load should be applied gradually and with the least possible jar, care bein also, to keep the loading uniform on opposite sides of the post, which sh always vertical. Levels should be taken at frequent intervals during the tion of the load. The level observed when the platform is first in positi be taken as zero and successive settlements referred to it. When the p unit load has been reached, no additional load should be added until no settlement is observed. After this, first 50 and later 100% overload added and the total and periodic settlements observed. If the settlemen a test-load of twice the proposed load is not excessive, the test is consider factory.

12. Topographical and Special Conditions

Excavations over Inclined Strata. In case the site of a proposed is on a slope, and especially if the slope is steep, there may be danger slip of the material forming the foundation-bed. (See, also, page 135. may occur if there is an inclined plane of separation between layers of th lying rock, or between the rock-surface and the material overlying t or if inclined strata or beds of clay occur below the foundation-bed. such locations are the more likely to occur if water is present, as th increases the weight of the soil and also reduces the COEFFICIENT OF F against sliding. Such conditions are frequently indicated by the appea springs or springy ground below the site. Where the base of the slope a stream or river there may be danger from the washing away of bank have been supporting the side slopes of the valley. In the case of deep with steep clay banks, or in any location where landslides have been k occur, great care should be taken to extend the footings to a bed that be affected by any landslide. It sometimes happens that there is a sl tinuous and general movement of the material forming the side slope of toward the center of the valley; but such conditions are rare, fortunatel general, no adequate protection is possible. In certain limestone fo there is danger from natural caves formed in the limestone by the a water.

Excavations Near Navigable Waters. When buildings are loca navigable waters, it not infrequently happens that dredging-operatio considerable distance induce a flow of fine sand or clay from strata un the adjoining banks. This has occurred where the existence of suc was not suspected. This danger is especially to be guarded against in localities adjoining waters which are, or may be, used as navigable st in locations near the water-front where it is likely that docks will be con

...age from Adjoining Excavations. Common and statute laws make ...l provision for the protection of property-owners against damage result... from the acts of others in making such excavations; but an owner has usu... control over such operations, whether on adjoining properties or streets, ... in general will prefer the assurance of safety to the possibility of damage ... building and the expense and uncertainty of a lawsuit. While it is not ... possible to guard fully against the effects of adjoining excavations, and ... the expense of so doing is not always justifiable, due consideration should ... to the matter. The following suggestions, therefore, may be of value.

...th of Adjoining Excavations. Footings adjacent to property-lines ...ated where there is a probability of future additions to a building, or ... of a building which adjoins property liable to become the site of building-...tions, should go down at least as deep as the maximum probable depth of ...jacent work. In estimating these probabilities, the character of the loca... should be taken into account. In medium-priced residential sections ... are rarely carried much deeper than 10 ft, a sufficient depth for a cellar ... height below grade. In high-priced residential sections it is not un... to have both a basement and a cellar, in which case a depth of cellar ... grade up to 20 ft may be expected. Cellars for residences are rarely ... below 10 ft, if in reaching that depth the excavation goes below the ...-level. In fact, a high water-level discourages deep excavation, not only ...count of the increased difficulty and expense of excavation but also on ... of the expense of waterproofing. In business sections, especially in ... of high ground-rents, there is an increasing tendency toward deep ..., especially in boiler-rooms, where clear heights of 20 ft and over are de... for modern water-tube boilers. The basements are frequently rentable ... figures for restaurants, vaults, stores, etc., so that in many instances the ... mechanical equipment of the building is housed below the basement in a ...ement and boiler-pit, the excavation for which extends down at least ... and in special cases 60 ft below the curb; and this notwithstanding the ... the water-level may be only from 10 to 20 ft below the curb.

...ers and Trenches as Affecting Foundations. In cities and towns ...ration should be given to the possibility of the construction of trenches ... streets. For the majority of localities it will be sufficient to consider ...bable depth of a sewer of the proper depth to serve the street. In other ... it will be necessary to consider the broader question as to the proba... of deeper excavations for trunk sewers, subways, etc. As such construc... are controlled by broad topographical considerations, no general rules can ... and the local city engineer should be consulted.

...dations Near Mines, Shafts, Wells, Etc. In mining-districts local ...ties should be consulted as to danger from the caving of OLD MINE-... No adequate provision can be made in the foundation against ...despread caving or subsidence as may result from mining-operations. ... cases, successive falls of rock-fragments from the roof may gradually ... voids left by the mining-operations, as the loosely piled fragments of the ... occupy more space as FILL than they did as part of the solid roof-mass. ...etimes happens that where the original working is deep, progressive ... of the roof fills all voids, and no surface-settlements result. In other ... overburden may settle as a solid mass, causing a settlement at the ... equal to the thickness of the old working. Precautionary measures may ... the filling in of the workings, a subject outside the limits of this chapter. ...se of an important building a local mining engineer should be consulted ...ssible, the location of the building changed to a safer site. MINING-

SHAFTS, DEEP WELLS, SHAFTS FOR TUNNELS, etc., may cause disturb the soil, but in such cases the settlement is generally concentrated aro shaft or well, and buildings at a reasonable distance are slightly affected.

Foundations Near Tunnels and Trenches for Railroads and Su In large cities the necessities of transportation are increasingly calling struction of underground RAILROADS, TUNNELS and SUBWAYS. Such const are generally planned to follow streets. Railroad tunnels for trunk li be expected to follow direct lines to centrally located stations or termina routes which avoid, as far as possible, difficulties of construction, conder of real estate and damage to high-priced properties. The depth of exc will generally be as shallow as practicable. Where the tunnel has to dip underneath some obstruction, the approach-grades will probably be at t imum or limiting grade of the particular section.

Relation of Subways to Foundations of the Most Important ings. In SUBWAY-CONSTRUCTION for rapid-transit passenger service, t can be operated on sharper curves and with steeper grades than would in the case of a trunk-line railroad. This permits the lines to follow the lines of the city streets. For traffic-considerations the locations general, follow the principal arteries of surface traffic, and stations will, eral, be located at intersections of important streets, where there is the congestion of population. As such conditions are caused by the exist trade-centers, and call for the construction of high buildings, it may re seen that the heaviest and most important buildings are most likely their foundations affected by the construction of a subway in their im vicinity. Where there is reason to apprehend the construction of su WAYS or TUNNELS, information should be sought as to the probable d the excavation, the depth at which water is encountered, the characte material, the probable width of the construction as affecting the use of s vaults, and the method to be employed in making excavations. Wh excavations for such tunnels and subways have been carried below th of the footings of adjoining buildings, as in Baltimore, Boston, Brooklyn, and New York City, buildings along the routes have been seriously a Such results have not been limited to any particular methods used in t struction of the tunnels, as even where the excavations were wholly, or in rock, serious damage has been done.

18. Loads Coming on the Footings

The Loads to be Considered in the design of the footings of a s are:

(1) **The Dead Loads,** or the loads due to the actual weight of the co structure, ready for occupancy.

(2) **The Live Loads,** or the loads due to the occupancy of the building to the weight of snow on the roof.

(3) **The Wind-Loads,** or the vertical components of stresses in the st produced by wind-pressure.

(1) **The Dead Load.** The dead load of any structure can be ac calculated. If the structure is properly designed the part of the de supported by each element of the foundation can be definitely stated. T dead load becomes effective as soon as the building is completed, and constant thereafter unless additions or alterations are made to or in th ture.

The Live Load. The live load of any structure is the sum of the roof- and floor-loads. In designing the roof and floors the calculations for are based on an assumed unit load which should be the maximum load, with the probable use of the structure, to which any portion of the floor may ever be subjected. The assumed live load is, therefore, probably greater than the average load for the entire area of a floor or the entire the roof. Moreover, as it is improbable that conditions of maximum will ever occur simultaneously on the roof and on all of the several it is probable that the maximum load on the footings will be less than the maximum loads on the roof and on the several floors.

Minimum Live Load for an unloaded building is zero.

Actual Live Load will vary from zero to a maximum, which maximum usually be less than the total assumed live load.

Ratio of the Probable Maximum Live Load to the Assumed Live Load in different buildings, so that no table or general rule can be given.

Probable Maximum Live Load. As it is important to know, approximately at least, the maximum live loads to which the footings will be subjected, this maximum may be only a fraction of the assumed live loads, the should make a careful study of the conditions of loading to which the will probably be subjected and estimate the probable maximum live for the entire building.

for Estimating Live Loads. (See, also, Chapter XXI, pages 718) In estimating the probable maximum live loads for different uses, the notes may be of value. In certain buildings the assumed unit load the roof and on parts of each floor may be reached at various times, is unlikely that the maximum loading of all parts of the building will at the same time. In buildings of many stories the probability of having loads on all of the floors at the same time decreases as the number increases.

Household and Office-Furniture weighs from 5 to 10 lb per sq ft of occupied. While safes, bookcases or filing-cases may produce local load- from 50 to 100 lb per sq ft, the average load on office-floors rarely reaches per sq ft.

Residences, Apartments and Parts of Hotels not used for public assemblies rarely loaded with more than 5 lb per sq ft of floor-area.

and Wholesale Stores require a large percentage of the floor-area for of salespeople and customers, and not over 50% of the floor-area is used storage of stock. In estimating the weight of miscellaneous stocks, an between the lightest and heaviest classes should be taken for the weight foot, and also, in figuring the total space occupied by stock, an average be taken between the maximum and minimum amount of stock carried. DRY-GOODS STORES the floor-load for the entire building may amount more than 25 lb per sq ft, but in WHOLESALE STORES, and especially in and hardware stores, the average load may greatly exceed this figure.

Workshops, Loft-Buildings and Buildings for Manufacturing, the actual will, of course, vary with the class of material handled and the weight machinery used, and no general estimate can be made. Where the character of the occupancy to be expected is known it is possible to make a close estimation of the weights of machinery, fixtures and average stock on each

Warehouses. In buildings used, in whole or in part, for STORAGE PURPOSES may be used for light, bulky materials which, when stowed so as to leave

gangways and working-spaces, will give a resultant load much belo
sumed load. On the other hand, the heaviest materials may be c
piled from floor to ceiling in defiance of building regulations, posted no
common sense. Raw materials or crated or baled materials can b
closer than miscellaneous articles, and are therefore liable to increase t

The Ratio of the Total Probable Maximum Live Load to the Total Live Load having been determined for the entire building, the probable n live load for any element of the footing may be readily obtained by mu the assumed or calculated live load for that element by this ratio.

(3) **The Wind-Load** is generally calculated on the assumption that may exert a uniform pressure, frequently taken at 30 lb per sq ft, on t external area of any side of the building. This assumption makes no d for the protecting influences of adjoining buildings. In a building of a is improbable that the maximum pressure will be reached over the entire area at the same instant of time, and consequently, if the assumed represents the maximum pressure, the average, at any time, will be l the calculated total.

General Effect of Wind-Pressure. The horizontal pressure of the wi to increase the load on footings on the leaward side of the building ar crease the load on footings on the windward side. In many buildings bracing, called wind-bracing, or other special construction, is used to the building from being deformed by the wind-pressure and to convert zontal stresses due to the wind-pressure into vertical components, acti defined lines of support, that is, into either uplifts or loads on certa piers or columns. Where the uplift on any element of the structure is the dead load on the same element, the uplift is ignored. Where the component increases the compression in any element it is called the WIND THAT ELEMENT of construction and on the corresponding footing. Th is generally based upon concentrating all of the wind-load on certain footings. If, on account of the general rigidity of the building, or on ac any other reason, the wind-stresses reach footings not designed to recei loads, the amounts figured on the external footings will be reduced cor ingly. It is probable that the maximum effect of the wind results from of impulses of short duration and that the effect of such pulsations partially overcome by the inertia and elasticity of the buildings; so resultant load reaching the footing may be only a part of the theoretical the instant during which the maximum pressure is exerted. (See, also, XXIX, Wind-Bracing of Tall Buildings.)

The Probable Maximum Wind-Load acting on the footing is, there than the theoretical load due to the maximum wind-pressure. If the wind-load represents approximately the maximum wind-pressure, as by a wind-gauge, it would appear safe to assume that only 50% of the wind-load would act to produce a settlement in the footings of a Some authors recommend that in proportioning footings all wind- ignored; but this, especially in the case of high and narrow buildings, festly improper. The minimum wind-load is negative, being actually from which the load may vary to the maximum, but the maximum reached only at rare intervals and will endure for a short period only.

The Combined Wind-Load and Live Load. It is improbable that t mum wind-load and the maximum live load will occur at the same ti consideration should be borne in mind when the estimate is being m the effective wind-load.

14. Assumed Loads Specified by Building Codes*

II. Requirements of Building Codes for Assumed Loads for Office-Buildings

City	Requirements
...a, Ga.	Live load, 75 lb per sq ft above 1st floor; 150 lb per sq ft on 1st floor Footings designed for dead load and 60% of live load and wind-load
...n, Mass.	Live load, 100 lb per sq ft. Wind-load, 30 lb per sq ft where erected in open spaces; in built-up districts, 25 lb at the 10th story, 2½ lb more for each succeeding upper story, up to a maximum of 35 lb to the 14th story and above
...lo, N. Y.	Live load, 70 lb per sq ft. Wind-load, 30 lb per sq ft. Foundations designed for the acting average loads in the completed and occupied building and not the theoretical or occasional loads
...apolis, Minn.	Live load, 75 lb per sq ft above the first floor; 100 lb for first floor. Wind-load, 30 lb per sq ft. Roof and top floor, full live load. For each succeeding lower floor, a reduction of 5% until 50% is reached, such reduction being used for the remaining floors
...mond, Va.*	Foundations designed for 60% of the live load
...ouis, Mo.*	Live load, 70 lb per sq ft; first floor, 150 lb. Loads carried by the soil, total dead load and 10 lb per sq ft of all the floor-area. Wind-load, 30 lb per sq ft
...Paul, Minn.	Live load, 60 lb per sq ft above the first floor. First floor, 125 lb. Wind-load, 30 lb. Roof and top floor, full load; for each lower floor, a reduction of 5% until 50% of the full live load is reached, when such reduced load shall be used for the remaining floors. Footings designed for dead load and live load
...innati, O.	Live load, 50 lb per sq ft above first floor; 100 lb for first floor. Live load reduced by 5% for each floor below the top until 20% is reached, when such reduced loads shall be used for remaining floors. Wind-load, 20 lb per sq ft above surrounding buildings
...go, Ill.	Live load, 50 lb per sq ft. 50% of the live load used for piles. Piers designed for 85% of live load on top floor and reduced by 5% for each lower floor until 50% is reached, when such reduced loads shall be used for the remaining floors. Wind-load 20 lb per sq ft
...York City*	Footings designed for 60% of the live load
...land, O.	Live load 60 lb per sq ft in offices proper. 100 lb per sq ft in halls, lobbies, etc. Footings for walls designed for 50% of live load. Free-standing columns designed for 80% of 100-lb load and 75% of 60-lb load. Wind-load 30 lb per sq ft; for free-standing structures in built-up districts 25 lb per sq ft at the 10th story and 2½ lb less for each lower story, and 2½ lb more for each higher story, until 35 lb is reached

...s are constantly changing. Richmond's new code gives floor-loads; St. Louis ...ed some values; New York City's new code gives floor-load values different ... of the former code.

Reduction in Assumed Loads. The building codes of various ci tain rules governing the assumptions to be made as to live loads and wi and these rules generally provide for some REDUCTION IN THE ASSUME Generally, it will be found possible to meet these requirements and at time arrange for the proper proportioning of the supporting areas. page 151, gives briefly the requirements of the building codes of several to assumed loads for office-buildings.

15. Proportioning the Supporting Areas for Equal Settlem

The Minimum Areas of Support. The actual dead loads and the live loads and wind-loads for each linear foot of wall and for each colu or other supporting element of the building down to the level of the having been calculated, a foundation-plan should be prepared giving th and center of action of all loads. For safety under the worst possible tion of loads, each footing should be ample to support the total of the de live loads and wind-loads coming on it. The MINIMUM AREAS OF SUP any footing are obtained by dividing the total of the dead loads, live l wind-loads by the safe supporting power of the foundation-bed. foundation-bed is rock, or can be considered as incompressible under load, the minimum areas so obtained may be used for the footings. pressible materials, or generally on all materials other than rock, th these minimum areas will not result in uniform settlements owing to that the actual live loads and wind-loads are not consistent with the live loads and wind-loads.

The Actual Loads on the Footings. In accordance with what previously said, let us assume that the dead load is constant, and th building under consideration the probable maximum live load is 50% assumed live load, that the probable maximum wind-load is 40% of the wind-load, and that on the completion of the building, for a short pe live loads and wind-loads reduce to zero. The ACTUAL LOADS ON THE would then be:

(1) Upon completion of the building, the dead load only;

(2) Under the maximum load due to occupancy and to snow on the dead load plus 50% of the assumed live load;

(3) When loaded as in (2) and subject, in addition, to the maximu able wind-action,

(*a*) The footings on the leaward side of the building will sustain dead load, plus 50% of the assumed live load, plus 40% o sumed wind-load;

(*b*) The footings on the windward side of a building will sustain dead load, plus 50% of the assumed live load, minus 40% o sumed uplift;

(*c*) Other footings will support the total dead load, plus 50% of sumed live load, plus zero wind-load;

(4) Intermediate conditions as to live loads and wind-loads will loadings intermediate between (1) and (3).

Variations in Unit Loads on Foundation-Beds. With such know tions it is, therefore, impossible to proportion the supporting areas so unit load on the foundation-bed shall be uniform at all times. If the ing areas are proportioned in the ratio of the dead load only, the buil completion, and before occupancy, will uniformly load the supportin and at that time all of the footings should show equal settlements; bu

[…], when the supporting areas have been subjected to the full effects of the […] and wind-loads, certain supporting areas, having a high percentage […] loads, or of live loads and wind-loads, will be subject to a higher unit […] and the corresponding footings will consequently settle more than other […] supporting a low percentage of live loads, or live loads and wind-[…].

[…]-Uniformity in Footing-Settlements. If, on the other hand, the sup[…] areas are proportioned on the basis of the dead loads, plus the maximum […], plus the maximum wind-loads, even if the MAXIMUM LOADS are the […] ACTUAL MAXIMUM LOADS, and not the FICTITIOUS ASSUMED LOADS, it is […] that upon the completion of the building and before occupancy, the […] areas having a lower percentage of live loads and wind-loads will […] higher unit load, and the corresponding footings will have settled more […] other footings supporting a high percentage of live loads and wind-loads. […] basis, the footings will not come to a uniform settlement until they […] subjected to the maximum live loads and wind-loads.

[…]itrary Rules for Proportioning Supporting Areas. Various ARBI[…] RULES have been recommended for the proportioning of the supporting […] to secure equal settlements. These rules generally provide for a reduc[…] the assumed live loads and wind-loads, but do not take into consideration […] that a large proportion of the total settlement of certain footings may […] place subsequently to the completion of the building and after other foot[…] have reached practically their full settlement.

[…]onal Rule for Proportioning Supporting Areas. The rule herein[…]commended provides not only for a reduction of the assumed loads on […] rational basis, but also for the proportioning of the footings for the mean […] instead of for the ultimate load, and it is believed that the resulting settle[…] will be as nearly uniform as possible. The rule is based on the propor[…] of the footings in accordance with the loads which will act on the […] at the time when all of the dead loads and one-half of the probable […] live loads and wind-loads exist. The reason for taking one-half of […] probable maximum wind-loads and live loads is that these loads vary from […] a maximum, the average being one-half of the maximum.

[…]vision for Variations in Loads. On the completion of the building […] before the live loads or wind-loads have gone on the footings, the settle[…] will not be uniform, because areas designed for a high percentage of live […] and wind-loads will have much less than their average load and will there[…] have settled less than footings having a low percentage of live loads and wind-[…]. When these same footings have been subjected to the maximum probable […] loads and wind-loads, the settlements will again be unequal, because the […] have been proportioned for only one-half of the probable maximum live […] and wind-loads; but the footings which originally were the highest will […] be the lowest. The inevitable movement due to the variation in the live […] and wind-loads will be equally divided, one-half of the settlement being […]ed to bring the footing to the level of a footing having the dead loads only, the other half of the settlement carrying it an equal distance below the same […]. In other words, the method provides for the least possible variation […] footings having different proportions of live loads and wind-loads.

[…] Mean Load. For lack of a better name, the loads taken for the pro[…]ing of the footings, consisting of the total dead loads, one-half of the […] maximum live loads and one-half of the probable wind-loads coming […] footing, will be called the MEAN LOAD.

The Mean Unit Load. The areas will be made such that the load foundation-bed due to the mean loads will be uniform, and this unifo which, in general, will be considerably less than the allowable unit load foundation-bed will be called the MEAN UNIT LOAD.

The Minimum Unit Load. The necessity for providing for th possible condition of loading is satisfied if the supporting area for all i is sufficiently large to support the total of the dead loads and the assun loads and wind-loads at the allowable unit pressure. The resulting a support are the MINIMUM AREAS, and any change in these areas neces make them proportionate to the mean loads must be effected by increasir areas rather than by diminishing any. Any mean unit load which wou when divided into the mean loads, areas, all of which would be larger t minimum areas, would serve as the mean unit load, but it is more eco to determine the LOWEST POSSIBLE MEAN UNIT LOAD which, when ap the mean loads, will give the least possible increase of the areas. This done by determining which one of the minimum areas carries the LEAS LOAD PER SQUARE FOOT. This area may be selected by calculating th load on each of the minimum areas, or more simply, by comparing th of assumed loads and a table giving the mean loads, and noting which has the LARGEST PERCENTAGE OF REDUCTION between the assumed load mean load. The resulting mean load on this footing will be the MINIMU LOAD which can be used as a MEAN UNIT LOAD.

The Method Reduced to Rule. The method can be reduced to follows:

(1) Prepare a table giving in vertical columns or table-divisions f footing, the dead loads, the assumed live loads, the assumed wind-loa the total of these three loads. This table is called the TABLE OF ASSUMED

(2) Prepare a similar table giving the dead loads, one-half of the ma probable live loads, one-half the maximum probable wind-loads and th of these three loads. This table will be called the TABLE OF MEAN LOAD

(3) By a comparison of the two tables, find the supporting area wh suffered the greatest percentage of reduction between the total assume and the total mean loads and find the unit load resulting from the mean l this area. This unit load will be called the MEAN UNIT LOAD.

(4) Divide the total mean load as given in the table of mean loads f footing by the mean unit load. The result will be the required AREA PORT.

Short Method for Determining the Mean Unit Load. From th going it follows that the MEAN UNIT LOAD can be obtained more directly by lowing rule. Find the supporting area which has suffered the largest per of reduction between the total assumed load and the total mean load and ply the allowable unit load on the foundation-bed by the ratio obtai dividing the total mean load by the total assumed load.

Illustrative Example. The following example is figured out more full is necessary in practice in order to fully explain the method and also to c the method with other methods frequently used and recommended. Ord the wind-loads on a building of the size and type assumed in the example w ignored, but they have been considered here to make the example compl

A factory-building (Fig. 2) is to have four floors above the basemen capable of supporting an assumed unit load of 200 lb per sq ft. The l the flat roof is assumed at 50 lb per sq ft. The horizontal wind-pressur sumed as a uniform pressure of 40 lb per sq ft, on the sides *AB* and *C*

tical component of the wind-pressure is to be taken care of by the foot-
f the side walls. There is also an interior self-supporting chimney and
ing shaft which is protected from the wind and which carries no floor-

undation-bed is a uniform, sandy material which is expected to compress
ly and at the rate of ½ in per ton of load per sq ft of supporting area.

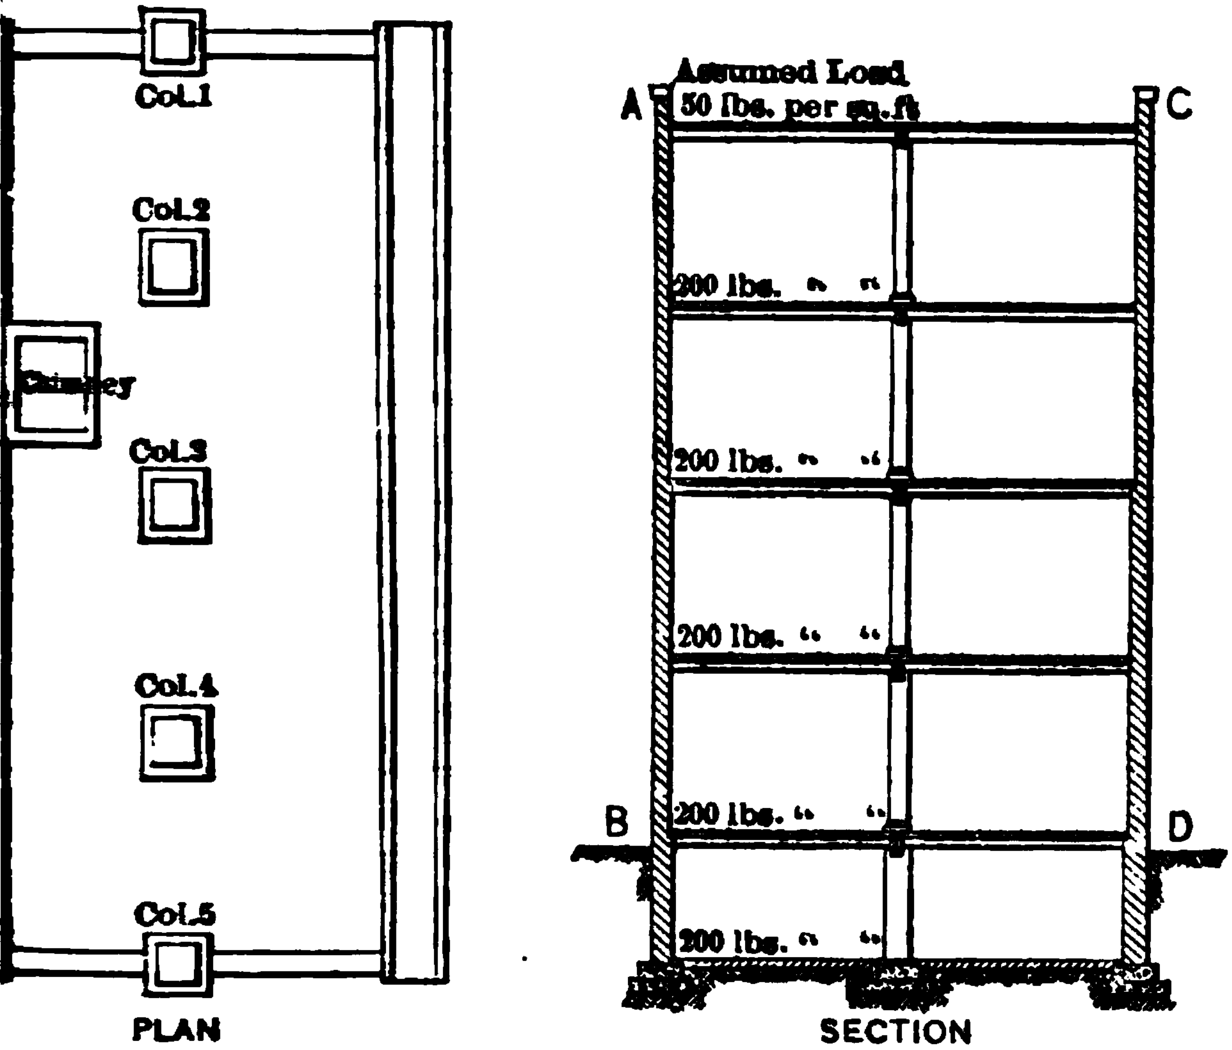

Fig. 2. Foundation-plan and Section of Factory-building

aximum unit load on the foundation-bed is taken at 4 tons, correspond-
a settlement of 2 in for the assumed load. The calculated dead loads of
uilding, including all construction down to the level of the footings, the
ation of the assumed live loads and the vertical components of the assumed
loads are given in Table III.

Table III. Dead Loads and Assumed Live and Wind-Loads

ement of footing	Division 1, dead loads only, lb	Division 2, assumed live loads, lb	Division 3, assumed wind-loads, lb	Division 4, total dead, live and wind-loads, lb
walls per lin ft....	14 000	8 400	2 000	24 400
mns 1 and 5......	137 500	160 000	....	297 500
mns 2, 3 and 4....	90 000	340 000	....	430 000
ney.............	320 000	....	....	320 000

columns are called divisions to avoid confusion with building-columns.

A careful study of the probable loading of the building shows that the ma
live loads at any one time will not exceed 60% of the total assumed liv
and that the maximum wind-loads will be less than 50% of the assume
loads, for the reason that the assumed wind-pressure is based upon the
recorded pressure on a limited area in an exposed situation, whereas t
posed building will be in a sheltered situation. Having, therefore, dete
the probable maximum live loads and wind-loads at 60% and 50% resp
of the assumed loads, the so-called mean loads, corresponding to loads h
between the minimum and maximum loads, will be one-half of the p
maximum loads, or 60% × ½ = 30% of the assumed live loads and 50
= 25% of the assumed wind-loads. Table IV gives the dead loads a
mean live loads and wind-loads separately, and the total of the dead loa
mean loads, which total is to be used in proportioning the areas for least
tion in settlement. This is known as the total mean load.

Table IV. Dead Loads, Mean Live and Wind-Loads and Total Dead Mean Loads

Element of footing	Division 5, dead loads, unchanged, lb	Division 6, one-half of 60% of assumed live loads, lb	Division 7, one-half of 50% of assumed wind-loads, lb	Divisi total loads
Side walls per lin ft....	14 000	2 520	500	17
Columns 1 and 5......	137 500	48 000	....	185
Columns 2, 3 and 4....	90 000	102 000	....	192
Chimney.............	320 000	....	....	320

Table-columns are called divisions to avoid confusion with building-columns.

Comparing the two tables it will be seen that the interior columns
building, columns 2, 3 and 4, had originally the largest percentage of liv
(no wind-loads), and have consequently suffered the greatest reduction
amount of total load. The minimum areas of support for columns 2, 3
and also for the other elements of the footings, are obtained by dividi
total assumed loads given in division 4, Table III, by 8 000, the all
unit load in pounds on the foundation-bed. The resulting areas are gi
division 9, Table V. No reduction can be made in these areas without e
ing the limitation that the most disadvantageous combinations of loading
ever improbable, shall not exceed the safe unit load. The adjustment
areas to the probable mean loading, as given in Table IV, the table of
loads, must be accomplished solely by increasing the sizes of certain footi

If we divide the total mean loads in division 8, Table IV, by the mir
areas given in division 9, Table V, we will get the mean load per squa
on the minimum areas for each element of the footing. The results gi
division 10, Table V, show that the mean load for columns 2, 3 and 4 i
3 568 lb per sq ft, while under the chimney the load is 8 000 lb per sq f
no reduction in area is permissible it is necessary to increase the footings
the chimney, side walls and columns 1 and 5 until the mean unit load
sponds to the mean unit load for columns 2, 3 and 5. This is done by di
the mean loads given in division 8, Table IV, by 3 568, the mean unit l

...ed for columns 2, 3 and 4. The resulting areas are given in division ... V, and are the areas which should be used.

...method of calculation can be shortened and reduced to a rule as follows. ... Table IV, the table of mean loads, with Table III, the table of assumed ... and find the element of support which has suffered the highest percentage ...tion between the total assumed load and the total mean load, and note ...sponding minimum area of support at the allowable unit load on the ...tion-bed. Divide the mean load for the same element of support by ...ber of square feet in the minimum area of support. The result will be ...it load for mean settlement. Then divide the mean loads for each ele... of support by the mean unit load. The results will be the required areas ... in Table V.

...le V. Mean Loads on Minimum Areas and Areas for Mean Loads

... Table VIII the footings are proportioned in the ratio of the MEAN LOADS. ...ch table, division 1 gives the dead load coming on the footings on the ...tion of the building. Division 2 gives the load coming on the footings ... the building is subjected to the maximum probable live loads and wind-... Division 3 gives the supporting areas in accordance with the assumed ... Division 4 gives the settlements for the unloaded building. Divi... gives the settlement after the addition of the maximum probable live ... and wind-loads.

...ation of Table VI. The method of proportioning the areas in the ... dead loads only, as recommended by C. C. Schneider* may, in the form ... be stated as follows:

* ...rticle on the Structural Design of Buildings, Trans. Am. Soc. C. E., vol. 54, ...

Compare the table-division of dead loads, Table VI, with the div
assumed live loads, find the element of support which has the highest pe
of live loads to dead loads, and note the corresponding minimum area of
at the allowable unit load on the foundation-bed. Divide the dead
the same element of support by the number of square feet in this minim
of support, and the result will be the unit load due to the dead load only
divide the dead loads for all other elements of support by this unit lo
the results will be the areas required. Thus, in Table VI, it is seen by
to Table III that columns 2, 3 and 4 have the greatest percentage of
to dead load, and their minimum area of support, as in Table V, is 53
Then, 90 000 ÷ 53.8 = 1 675 lb, the unit load due to the dead load onl
area for columns 1 and 5 is 137 500 ÷ 1 675 = 82.1 sq ft. The process
lar for the other elements.

Table VI. Footings Proportioned in the Ratio of the Dead Loads (

Probable settlement where supporting areas are proportioned in the rati
dead loads only

Maximum variation, loaded....................			....	....	

Table-columns are called divisions to avoid confusion with building-columns.

The calculations for settlements are readily made, when the amount
pressibility of the foundation-bed is known, by multiplying the unit load
foundation-bed of each element of support by the amount of compress
the foundation-bed per unit of load. Thus, in the above example the
of compressibility is given as ½ in per ton. In Table VI the unit load
dead loads for each element of support, are the same, or 1 675 lb = 0.
per sq ft, which, multiplied by ½ = 0.42 in. Similarly, the unit load
maximum probable loads for each element of support are determined,
loads, in tons, multiplied by one-half, give the settlements in inches as
division 5 of Table VI.

Explanation of Table VII. The areas given in Table VII are ob
dividing the total maximum dead loads, live loads and wind-loads (T
by the allowed unit, 8 000 lb per sq ft, and are the minimum areas given
V. The settlements for the loaded building are based on the maximum
loads as given in division 2 of Table VII.

Table VII. Footings Proportioned in the Ratio of the Total Assumed Loads

Probable settlement where supporting areas are proportioned in the ratio of total assumed loads

Element of footing	Division 1	Division 2	Division 3	Division 4	Division 5
	Dead loads only, lb	Maximum probable loads, lb	Areas, sq ft	Settlements

Table-columns are called divisions to avoid confusion with building-columns.

…planation of Table VIII. The areas in Table VIII are obtained as …ly explained and as given in division 11, Table V, and the methods used …termining the settlements are similar to those used for the preceding … In Table VIII it will be noted that columns 2, 3 and 4 have a settle… of 1.36 − 0.42 = 0.94 in, as a result of the addition of the live loads and …loads. Half of this settlement is required to bring these footings down to …level of the chimney-footing, and the other half of the settlement brings

them below the chimney-footing. There is no way to prevent this sett of 0.94 in, but its effect on the building is reduced to a minimum by hav settlement of the footings of columns 2, 3 and 4 start above the chimney- and finish below it. The chimney-footing does not change its elevatio the completion of the building, and compared with it, the variation in l the other footings is the minimum. In their mean position, half-way i movement, these other footings will be at the same level as the chimney-f

16. Determining the Supporting Areas

General Requirements. In laying out the AREAS OF SUPPORT for any ture it should be borne in mind, as previously explained, that (1) the t the dead loads, assumed live loads and assumed wind-loads should not lo foundation-bed in excess of the allowable load on it; (2) when the foun bed is compressible the areas of support should be calculated by the mea mean loads; and (3) the center of gravity of the supporting area should c with the center of action of the load to be supported. To these may be a further condition that (4) economy will be furthered by keeping the su ing areas simple in outline and by arranging each area as compactly as p around the center of the load to be supported.

(1) The first condition is necessary in order to provide that no possib dition of loading will exceed the allowable pressure on the foundation-be

(2) The second condition provides for making the settlements of di footings as nearly equal as possible.

(3) The third condition provides that the settlements of each footin be uniform, that is, that the footing shall not settle out of level.

(4) The fourth condition provides for economy in design in the footin and for economy in making the excavation for the footing, especially in t of deep excavations requiring sheathing for the protection of their sides.

In the case of a free-standing structure, the total load of which is not in of the supporting capacity of the entire area of the building at the sa load on the foundation-bed, it will generally be possible to arrange simp porting areas whose centers will correspond with the centers of the loads disposition of such areas is considered in succeeding paragraphs in the sions of CONCENTRIC LOADING. In buildings having restricted sites, walls or columns are placed close to adjoining property-lines, it will fre be impossible to arrange for simple concentric loadings and necessary offset footings, cantilevers or other devices to transfer the loads to sup areas located on the property. Such supporting areas are discussed in s ing paragraphs relating to ECCENTRIC FOOTINGS.

Footings with a Concentric Load. In order to have the load foundation-bed uniform under a footing it is necessary that the center c ity of the supporting area should coincide with the center of gravity of th otherwise the area is said to be ECCENTRICALLY LOADED and the resulti on the foundation-bed will not be uniform. Any variation in the loadi compressible foundation-bed under a footing will result in an unequal set of the footing and this in turn will result in unequal stresses in the wall, column supported by the area.

Wall-Footings with Concentric Load. In the case of a WALL, th should project an equal distance on each side so that the center of g the supporting area will coincide with the center of gravity of the wa the loads transmitted by the wall. The width of the supporting are vary with the load on the wall, irrespectively of any change in the thi the wall

ing for a Concentric Isolated Load. In the case of a SIMPLE CON-ED LOAD, as, for example, a load from a COLUMN or PIER, the footing be CIRCULAR, SQUARE, RECTANGULAR, or IRREGULAR in outline, but the of gravity of the area must coincide with the center of gravity of the load. mically the CIRCULAR SHAPE gives the most economical footing, as the ting areas extend radially the least possible distance from the center or of the load. Where deep excavation is necessary the circular form may itself to an economical method of excavation, as, for example, when cylin-l piers are sunk by the pneumatic method or by dredging. In general, ver, for ordinary footings the RECTANGULAR FORM is preferable, in that it itself to an economical arrangement of grillage-beams. The SQUARE is most economical rectangle as the sum of ending movements in the grillage and s is reduced to a minimum.

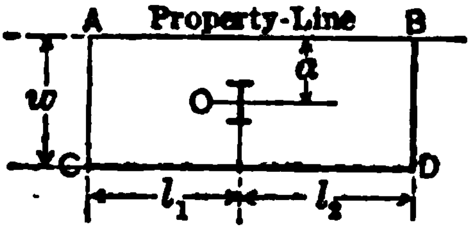

Fig. 3. Elongated Supporting Area. Concentric Load

ngated Supporting Areas. When the rting area for an isolated load cannot be a circle or a square, for example, when quare or the circle would overlap an ad- g property-line or interfere with an ad- g supporting area, the necessary area frequently be made RECTANGULAR in form, as *ABDC* (Fig. 3), having a h w, twice the distance a between the center of the load O and the ng line *AB*.

e required length l equals the required area divided by w and the area ld be centered on O, that is, l_1 must equal l_2.

mbinations of Simple Areas. Two Adjacent Isolated Areas. When ing supporting areas overlap or when, for other reasons, it is desirable to NE ADJACENT FOOTINGS, the best arrangement may be obtained as follows: ing the supporting area required for each of two adjacent concentrated and the distance between the centers of the loads, the sum of the two should be divided by twice the distance between the load-centers. The ent will be the width or the dimension of the required rectangle of sup- taken at right-angles to the line connecting the load-centers; and the dimension of the rectangle will be twice the distance between the load- s. The center of the area should be placed so as to coincide with the r of gravity of the two loads, when it will be found that each load will centric with its own area of support. Where a row of columns requires which nearly overlap, the COMBINATION OF THE AREAS frequently results in my in excavation and form-work.

porting Area for a Concentrated Load in the Line of a Wall. or more concentrated loads are carried in the line of a wall the ADDITIONAL TING AREAS required for such concentrated load may be provided in of two ways.

If the concentrated loads rest on the wall, as, for example, when the wall s the ends of girders and when the conditions are such that the con- ed loads are distributed along given lengths of it, then, all that is neces- s to increase the width of the footing for the given lengths sufficiently to for the total of the uniformly distributed and concentrated loads.

If a concentrated load is on the center line of the wall but cannot be dis- d by the wall, as when a considerable load is carried by a pier or column level of the footings, then one-half the additional area for the concentrated ould be placed on either side of the wall-footing, so that a line connecting ters of the two areas will pass through the center of the load. In general

it is desirable that the additional areas, together with the area for the wal between them, should APPROXIMATE A SQUARE. Knowing the width footing required to support the wall and the additional area required to s the concentrated load, the length of the side required square can be determined by the fol formula (Fig. 4):

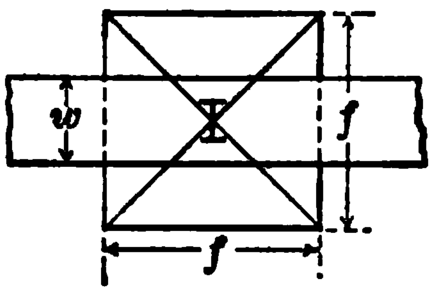

Fig. 4. Square Supporting Area. Wall and Concentric Isolated Load

Let w = the width of the footing;
A = the area required to support the c trated load;
f = the side of the square which will s a length of wall equal to f, an provide an additional area equa
Then

$$f = \tfrac{1}{2} w + \sqrt{A + \tfrac{1}{4} w^2}$$

Supporting Area for Concentrated Load not in the Center Lin Wall. The same additional supporting area is required for this as for centrated load on the center line of a wall, but the total area must be unequally between the two sides of the wall-footing, the larger portion being placed on the side of the eccentric load. The simplest way to determine the location of the supporting areas for this combination is to determine the size of the required square as if the concentrated load were concentric with the center line of the wall. The next step is to calculate the load due to the wall for the length of this square and determine the location of the center of gravity of the combined loads, that is, the center of gravity of this wall-load and the concentrated load. The center of the supporting area placed concentrically with the center of gravity of the combined load Fig. 5 let

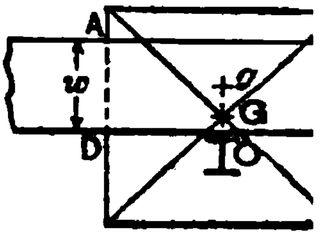

Fig. 5. Square Sup Area. Wall and tric Isolated Load

w = the required width of the wall-footing;
O = the concentrated load;
A = the area required for the support of the concentrated load.
as before, the length of the side of the required square will

$$f = AB = \tfrac{1}{2} w + \sqrt{A + \tfrac{1}{4} w^2}$$

The center of gravity of the wall-load contained between the lines A BC is at g, and the amount of the load is evidently the load per foot mu by the distance $AB = f$. Knowing the positi amount of the loads at O and g, the center of g of the combined loads is determined, say at G. fixes the center for the square.

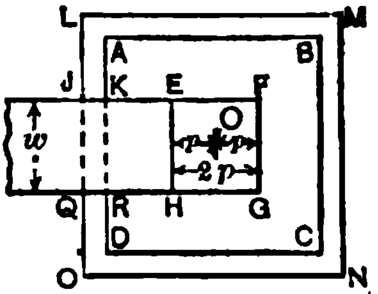

Fig. 6. Square Supporting Area. Isolated Load on End of Wall

Supporting Area for a Concentrated Lo the End of a Wall. A somewhat different tre is required for this, but the supporting area n best determined as follows (Fig. 6): Knowi width w of the footing required for the support wall, the additional area required for the conce load O and the distance p from the center of the c trated load from the end of the wall, proceed in this way. Determine the whose area corresponds to the sum of the areas required for the supp the concentrated load and for a length of wall equal to twice the projection wall beyond the center of the concentrated load. Plot this square $ABCD$

ation-plan and also the total area required for the support of the wall. square $ABCD$ includes an area sufficient for the support of the concentrated load for a section of the wall $EFGH$ corresponding to a length of wall equal to the projection p, multiplied by the width of the footing. It is evident the area $KEHR$ is loaded both by the wall and the concentrated load; in er words, that the square $ABCD$ is too small by the amount of the rectangle HR. The required square $LMNO$ will be approximately the square which contain the original area $ABCD$ plus the area $KEHR$, plus twice the area IQ. The length of the side $LM = MN$ will be approximately the length he original square plus one-half of the area $KEHR$ divided by the length he original square. The resulting square should be moved from the posi-shown on the drawing so that its center coincides with the center of ity of the combined concentrated load and the wall-load back as far as the re goes on the wall. A further approximation may be necessary where acy is required. The final result should be that the area of the square NO should be sufficient to support the concentrated load O and that portion he wall-load $JFGQ$ resting on the square, and that the center of gravity of square should coincide with the center of gravity of the combined loads.

17. Offset Footings

pporting Areas for Non-Concentric Loads. When walls, columns, or s are placed close to property-lines the required supporting areas cannot laced concentrically with the loads without lapping the property-lines. In such cases urse must be had to some method which will sfer the loads to supporting areas not con-ric with the loads. An attempt to accomplish result, the method known as OFFSETTING THE ING has been largely used, especially for side s adjoining property-lines. While theoreti-faulty, if not useless, it is indisputable that ET FOOTINGS have generally served the pur-for which they were designed. In the typical truction a cellar wall rests on a course of con-e or of flat stones forming a footing course iderably wider than the wall, the projection g entirely on one side of the wall. The load g on one side of the center of the footing s the supporting area unequally. The VARY-LOAD on the supporting area can be calculated llows: In Fig. 7 let

Fig. 7. Offset Footing. Varying Pressure on Foundation-bed

W = the total load per unit of length coming on the supporting area;
E = the eccentricity of load, that is, the distance between the center of the load and the center of the supporting area;
L = the width of the footing = the width of the supporting area = AB;
R_1 = the unit load, or pressure on the foundation-bed at A, the edge of the footing nearest the load;
R_2 = the unit load, or pressure on the foundation-bed at B, the edge of the footing farthest from the load;
y = any ordinate, from A to B.

hen the AVERAGE PRESSURE on the foundation-bed will evidently be W/L. essure at A, the edge nearest to the point of application of the load, will

be $K_1 = W/L\,(1 + 6\,U/L)$, or the MAXIMUM LOAD will equal the avera
plus six times the average load multiplied by the ratio of the ECCEN
divided by the width of the footing.

Similarly, the pressure at *B*, the edge farthest from the point of app
of the load, will be $K_2 = W/L\,(1 - 6\,U/L)$, or the MINIMUM LOAD equ
average load minus six times the average load multiplied by the ratio
eccentricity divided by the width of the footing.

When the ECCENTRICITY equals ⅙ the width, the pressure at *B* becom
If the eccentricity exceeds ⅙ the width there will be an uplift at *B*, or th
ing will have a tendency to overturn. This relation is generally expre
saying that to avoid an upward reaction the
line of the load must fall within the MIDDLE
of the base.

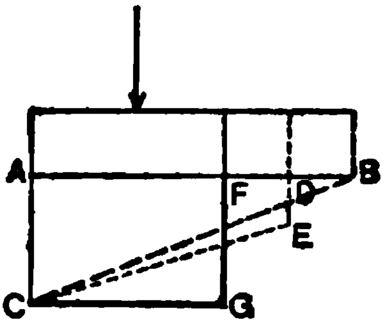

Fig. 8. Pressure-diagrams for Footings

Load-Diagrams for Offset Footings. In
diagram (Fig. 8) the figure *ADEC* represe

footing *AD* and the load *AC* is the maximu
missible load, then the area *ADEC* represe
maximum support afforded by the footing *A*
the width is increased until the load falls on t
of the middle third or to the width *AB*, th
load at *B* is zero and the support is represented by the triangle *A*
area of which is less than the area *ADEC*. Moreover, if the w
the footing is reduced until its center is concentric with the load-cent
the load-diagram becomes *AFGC*, the area of which is greater than eith
or *ADEC*. From the foregoing it is evident that any advantage gai
offsetting the footing must be obtained at the cost of concentrating the
given to the wall away from the center line of the wall.

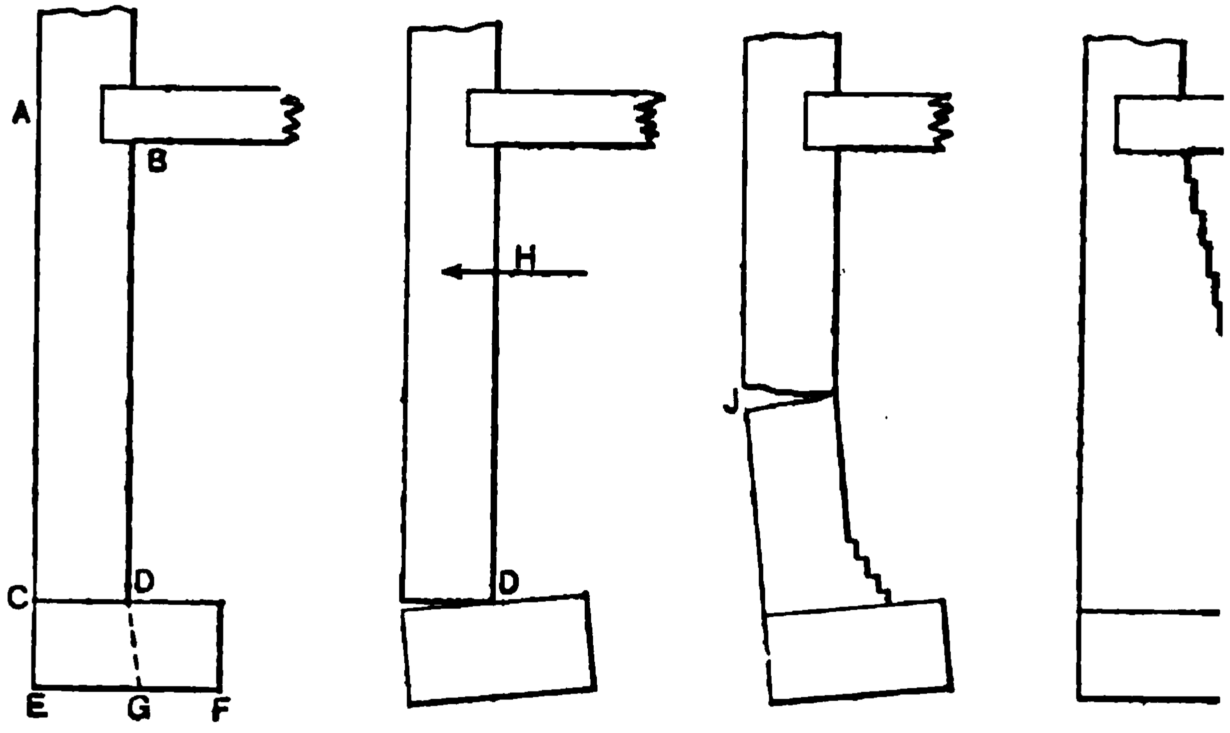

Fig. 9 Fig. 10 Fig. 11 Fig.

Figs. 9, 10 and 11. Eccentric Loading and Tendencies to Failure Due to Of
Footings; Fig. 12. Improved Type of Construction

Eccentric Loading Due to Offset Footings. In Fig. 9, represe
simple case of ECCENTRIC LOADING due to OFFSET FOOTINGS, the load
foundation-bed at *E* is perhaps twice the average load and at *F* abo
Under these conditions the projecting portion of the footing may shear,

along the line DG. If it does not shear and if there is any settlement to the load, the settlement will be unequal and the footing course will tend rotate into the position shown in Fig. 10. The entire load will then be transferred through the inner lower corner D of the cellar wall, rendering the wall stable and developing a tendency to move in the direction H.

The cellar wall may successfully resist this tendency by its own rigidity aided by the first-floor beams acting as ties or by the external resistance afforded by an abutting wall or bank of earth, or it may partially or completely fail developing a horizontal crack as indicated in Fig. 11 at J.

In this figure it will be noted that the base of the wall itself is offset. This is done to prevent the separate rotation of the footing course; but this construction does not diminish the TENDENCY TO ROTATION of the entire base of the wall and to the formation of a crack at J.

An improved type of construction is illustrated in Fig. 12, in which the floor-beams are anchored into the wall and the cellar wall has a continuous stepped offset from the level of the footing up to the level of the beams. The beams should evidently be arranged as tension-members, should run across the building and should be anchored in the opposite wall. While this method may have some effect it is of doubtful efficacy and should never be used for piers.

18. The Use of Cantilevers in Foundations*

Application of the Principle of the Lever. The use of the CANTILEVER, transferring a load to a supporting area not concentric with the load, is based on the PRINCIPLE OF THE LEVER and involves a girder or cantilever connecting two loads, and a supporting area or areas the CENTER OF ACTION of which is between the two loads. Part or all of the load on one side counterbalances the load on the other side of the center of the supporting area.

Illustrative Example. If an exterior column A (Fig. 13) carrying a load of 400 tons and requiring 100 sq ft of supporting area, at 4 tons per sq ft, the column-center being 18 in from a property-line PP which forms the limit of the building site, it is evidently impractical to employ a concentric footing 3 by 33⅓ ft for its support. If, however, a sufficient counterweight can be found in the shape of an adjacent interior column-load, as at B, the exterior load can be transferred by a girder or cantilever construction $CDEF$ to a supporting area MN lying between the two loads, and entirely within the limits of the property.

In Fig. 13 let PP represent the property-line, A the center of the load on column A, and B the center of the load on column B. Let the load on A be 400 tons, on B, 200 tons and the distance AB between centers, 20 ft. Assume that a rigid girder $CDEF$ supports and connects the two columns. If now a fulcrum or point of support G is provided for the girder at some point between A and B, the load on that point can be readily determined from the PRINCIPLE OF THE LEVER by multiplying the load on A, 400 tons, by the distance AB, 20 ft, and dividing the product by the distance BG, 19 ft; or, the load on G = $400 \times 20/19 = 421$ tons +. The area required for the support of this load, at 4 tons per sq ft, is $421/4 = 105\frac{1}{4}$ sq ft. The uplift at B, or the part of the load B required to counterbalance the overhanging load A is, from the principle of the lever, the product of the load A by the lever-arm AG divided by the lever-arm BG. The load on the footing for B is the difference between the original load and the uplift; but in view of the possibility of a reduction in the load A, which would decrease the uplift at B, it is well to provide for a possible increase in the load B.

* See, also, Chapter XIX, pages 678 to 680, for an example of a Continuous Girder in a Foundation.

Determination of the Area of Support. In determining the AR SUPPORT for A, having assumed one dimension of the supporting area twice the distance GP, or say 5 ft, the other dimension will be 105¼ sq ft/ ft ½ in. If the length 21 ft ½ in, as determined, is found to be excessiv

Fig. 13. Cantilever Foundation-construction

the point G must be moved to the left and the corresponding length of porting area must be determined as before. When the length of the sup area for the fulcrum of the cantilever is limited, so that the length pa the property-line is fixed, the width of the area can be determined experin or by the use of the formula

$$X = (L + u) - \sqrt{(L + u)^2 - 2\,WL/lS}$$

in which

L = the distance between centers of the two loads;
W = the load nearest to the property-line;
l = the length of the supporting area,
S = the unit load on the supporting area; and
u = the distance between the center of action of the load to be can and the edge of the supporting area nearest to the proper

If the position of the center of gravity of the load A combined w part of the load on B which is borne by the cantilever is determined, i found to coincide with the fulcrum or point of support G of the cantile demonstrating that the use of the cantilever provides a means of co two loads so that their center of gravity falls on the center of a suppor not concentric with either load.

The Grillage Fulcrum. Of course in practice the KNIFE-EDGE shown in the diagram is not used The bottom flange of the girder the cantilever rests on the DISTRIBUTING GRILLAGE directly, as is shown i which may be considered a typical arrangement.

The Girdering-Method for Two Equal Loads. When it is de support two or more adjacent concentrated loads on a single suppor

method called GIRDERING is employed. In the case of two concentrated ds, let A and B (Fig. 15) represent two columns. Let W_1 represent the load A and W_2 represent the load on B. Let D represent the distance between centers of the two loads. Let G represent the center of gravity of the comed loads. Let r represent the allowable unit load on the foundation-bed. e required area of support will be $(W_1 + W_2)/r$. This area may be of any

the distance D between the columns plus twice the extension e. Knowin length of the required area the width w is determined by simple division.

The Girdering-Method for Two Unequal Loads. In the case of col not equally loaded, the SUPPORTING AREA may be a TRAPEZOID, as in Fig the center of gravity of which must coincide with the center of gravity of loads. Knowing the sum and distance apart of the loads and the area for

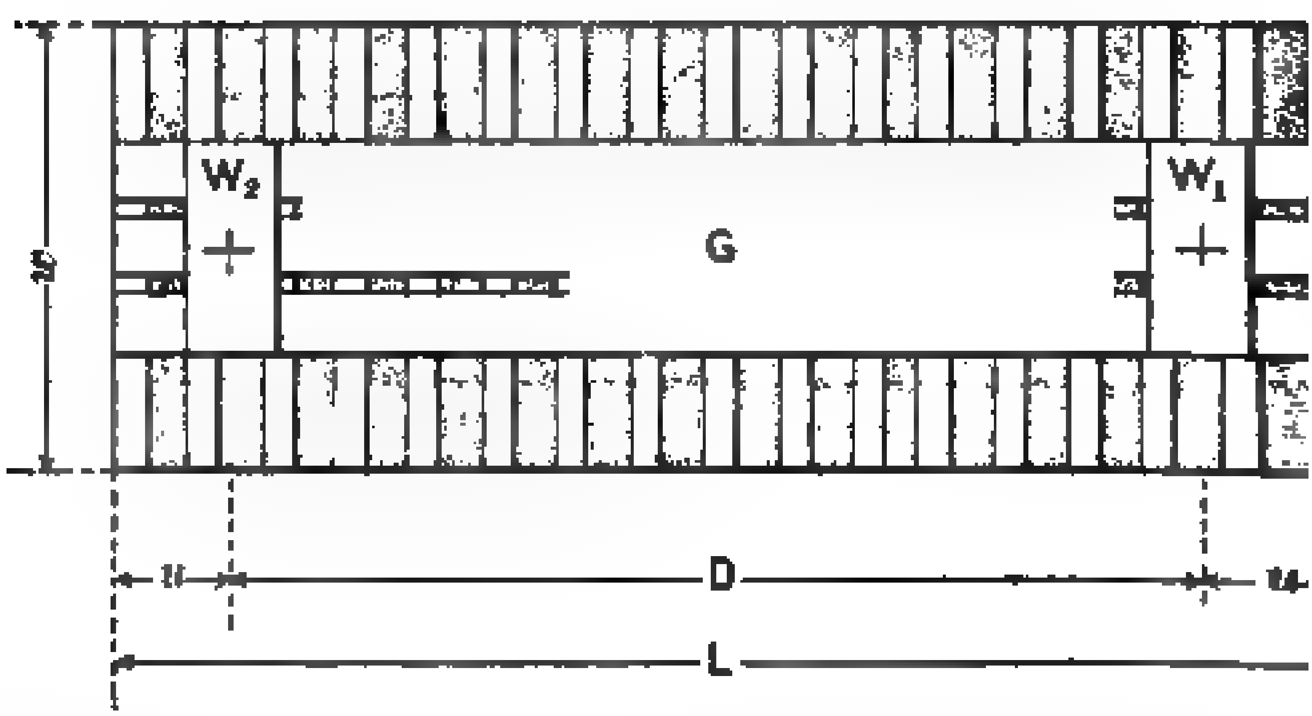

FIG. 15. Girdering-method of Foundations. Two Equal Loads

support, and fixing the total length L of the footing in accordance wi requirements that the footing shall not project beyond the line PP, the of the footing at the small and large end, a and b respectively, can be deter as follows: Let B represent the distance from the small end of the tra to the center of gravity of the two loads and let A represent the area trapezoid. Then

$$b = [2A/L] \times [(3B/L) - 1]$$
$$a = [2A/L] \times [2 - (3B/L)]$$
$$A = [(a + b)/2] \times L \quad \text{and} \quad a + b = 2A/L$$

For practical reasons the distance d should be made as small as possibl

Cantilevering an Exterior Wall. In the case of a wall the same principles apply, but the cantilevering effect must be distributed along the length of the wall. This can be accomplished by placing a girder under the wall, the girder in turn resting on the cantilever, or by using a number of cantilevers arranged

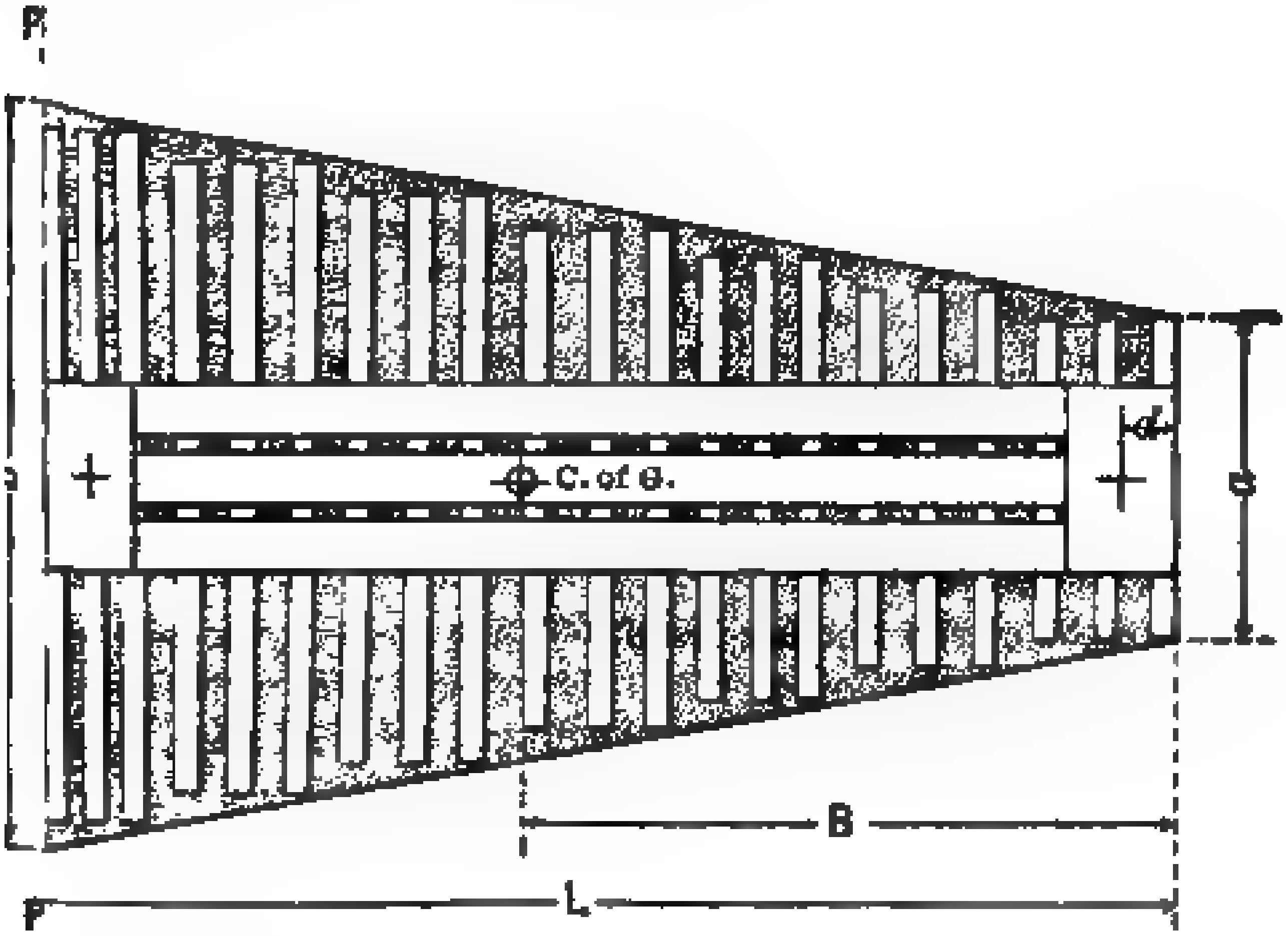

Fig. 16. Girdering-method of Foundations. Two Unequal Loads

in shape and radiating from the interior load-center. In narrow buildings cantilevers may run from wall to wall.

Double Cantilevering. The considerations controlling the design of the bearing areas required are the same as outlined in the preceding paragraphs.

10. Stresses in Footing Courses

Size and Form of Footing Courses. The footing courses of all walls and piers should be larger than the superimposed construction in order to secure STABILITY AGAINST OVERTURNING and to reduce the UNIT LOAD on the foundation-bed. When the change in size is accomplished abruptly as when a wall rests on a grillage or a slab of plain or reinforced concrete the footing is called a SPREAD FOOTING. When the base of the wall is thickened by means of offset

courses so that its bottom course is substantially as large as the footing the construction is known as a STEPPED FOOTING. It is evident that r and fast line can be drawn between the two classes. Whatever the form footing is it must be strong enough to distribute the more or less conce load coming on it, into a uniform pressure or load on the foundation-bed

The Unit Loads of Footing Courses. If the load on the upper of a footing course is uniformly distributed the intensity of the load, or i words the UNIT LOAD ON THE FOOTING, is obtained by dividing the total l the area of the base of the wall, pier, or other construction at that level load on the foundation-bed should be UNIFORMLY DISTRIBUTED and in the foundation-bed is compressible and the load concentric with the sup area, it may safely be assumed as uniform, since a compressible mater adjust itself until the loading at different points is substantially uniform unit load on the foundation-bed is evidently the total load divided by t porting area. If the area of the footing course varies between the top a tom of the footing the INTENSITY of the load will vary, and if uniformly distr the unit load at any level is obtained by dividing the total load by the the footing at that level.

The Weight of the Footing Itself. This is generally so small whe pared with the superimposed loads that it may be ignored without seriou

The Transmitting of Loads by Footings. If we neglect the we the footing we can consider the footing course as transmitting the impos to the foundation-bed or as being subject to two equal loads; one, the IMPOSED LOAD, more or less concentrated on the center line of the footi acting downward; the other, the REACTION due to the loading of the foun bed, uniformly distributed over the supporting area and acting upward. loads or forces being equal and opposite in direction, the stresses devel the footings are due to the differences in the distribution of these loa the footing courses simply act to convert concentrated into distributed l

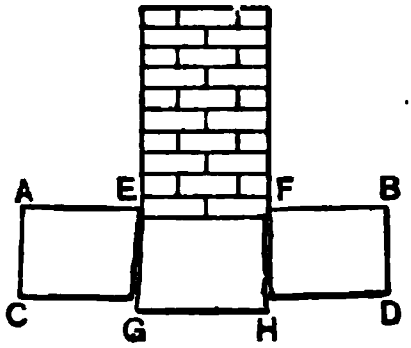

Fig. 17. Failure of Footing by Shearing

Manner of Failure of Footings. A footi fail in several ways: (1) by SHEARING; (2) by CRUSHING; (3) by SPREADING; and (4) by B OR RUPTURE.

(1) Failure of Footings by Shearing. ' illustrated in Fig. 17, showing a wall the we which has caused it to SHEAR along the lin and FH.

The force tending to cause SHEAR is the weig to the wall less the reaction of the foundation-b ing on the under side of the section $EFGH$. Si load is supposed to be uniformly distributed this is equivalent to the p of the area corresponding to the width CD minus the width GH times the of the wall considered, by the unit loading on the foundation-bed.

For a 1-ft length of wall the force causing shear, S, is

$$S = W\,(l - w)/l$$

in which W = the load due to wall per foot of length in pounds;
l = the width of footing;
w = the width of base of wall.

Or, since

$$W/l = U = \text{the unit load on the foundation-bed in pounds per squa}$$
$$S = U\,(l - w)$$

U is in terms of feet, l and w also must be in feet. The resistance to shear, under the conditions illustrated in Fig. 17, taken for a 1-ft length b of the is determined by the equation

$$R = 2 \times d \times b \times f$$

which f = the safe resistance of the material to shear, in pounds per square inch;
d = the depth of the footing in inches; and
b = the length of wall considered = 12 in.
ing $S = R$, we have

$$2\,dbf = U\,(l - w)$$

since $(l - w)/2$ = the projection of the footing

$$UP = 12\,df$$

depth of the footing, therefore, must not be less than

$$d = UP/12f$$

which P is in feet.

ar in Footings of Piers and Columns. FAILURE BY SHEAR is most likely occur in footings for piers and columns. The FORCE TENDING TO CAUSE is the total load on the column or pier less the reaction of the foundation-on the area immediately under the column-base. The resistance offered is ined by multiplying the perimeter of the column-base by the depth of the ing and by the allowable unit shear. When the area of the column-base all, the entire load may be taken as producing shear. When reinforced ete is used for the footing, there must be a sufficient number of stirrups to care of the shear. (See Chapters XXIV and XXV.) Where steel beams employed the cross-section of the beams must be sufficient to take care of shear, otherwise additional web-plates should be added, as is explained in ers XV and XX.

Failure of Footings by Direct Crushing. The failure of footings DIRECT CRUSHING of the materials composing the footings rarely, if ever, rs. Where, however, the concentrated load, due to a pier or column, is orted by beams or girders which have thin webs, the webs may fail by ling. Such beams or gird- should have their webs re- ced by vertical STIFFENERS y additional WEB-PLATES, and spaces between the beams ders should be filled with ete or grout. Where the transmitted by the column- exceeds the safe unit load the material of the footing area of the column-base may increased, or a block of granite be interposed between the ete or masonry footing and base of the columns. In case, however, such granite should be considered as a footing course and designed to resist bend- by formulas hereinafter given.

Fig. 18. Failure of Footing by Spreading

Failure of Footings by Spreading. Failure of the footings by SPREAD- may occur under walls or piers, as shown in Fig. 18, especially when the

foundation-bed is of clay or other yielding material, which has, under th of the footing, a tendency to FLOW along the lines indicated by arrows i figure. This tendency should be provided against by making the bottom continuous and adequate to resist the tension. Vertical joints, such a made in footings composed of masonry, are sources of weakness, and shou avoided. The TENDENCY TO SPREAD is greatest in footings having a spread is wide compared with the width of the superimposed wall or other constru The writer knows of at least one important footing which has failed in this the cracks in general following the joints of the masonry substantially as in Fig. 18.

(4) **Failure of Footings by Bending or Rupture.** A footing may f BENDING OR RUPTURE as a beam or girder. In the case of a wall, if the ing bends, as shown in Fig. 19, the concentration of the load on the lower

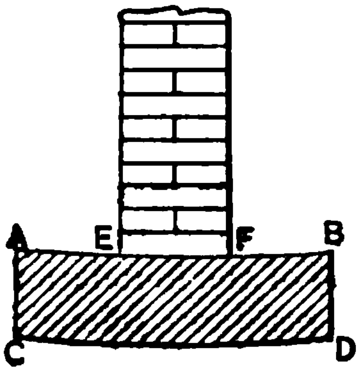

Fig. 19

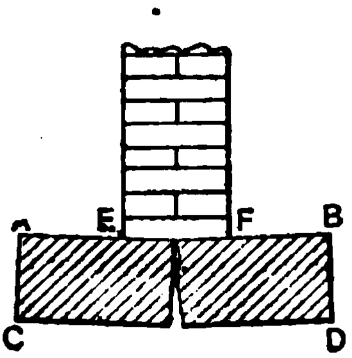

Fig. 20

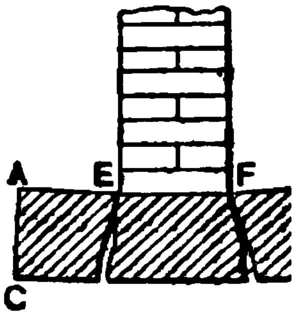

Fig. 21

Figs. 19, 20 and 21. Failures of Footings by Bending

of the wall, as at E and F may cause the base of the wall to fail. This poss should be borne in mind in designing footings where the load on the wa proaches the allowable unit load for the material composing it, and esp where the width of the footing is much greater than its own width.] footing fails by RUPTURE the rupture may occur either under the center l the wall, as in Fig. 20, or at points close to the outer edge of the wall Fig. 21. Fig. 20 illustrates the objection to using a footing course com of masonry or stones which do not extend the full width of the footing. joints in such construction prevent the footing course from acting in TE and the footing as a whole from acting as a BEAM.

20. Methods of Calculating Bending-Stresses in Wall-Footin

Assumptions Made in Determining Bending-Stresses in Foo

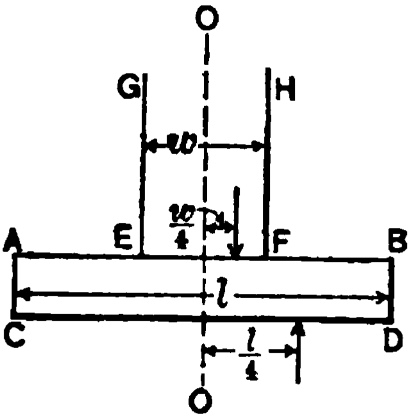

Fig. 22. Bending-stresses in Footings. First Method

Two methods for the calculation of the BEN STRESSES IN FOOTING COURSES are in genera Both are based upon the assumption tha REACTION of the foundation-bed is UNIFORM. the methods differ in the assumption made how the footing course and the base of the structure act. Neither assumption can be h be wholly correct.

The First Method of Determining Ben Stresses in Footings. This method is based the assumption that the pressure of the wall c footing is uniform over the area and remains so times.

If, in Fig. 22, $ABCD$ represents a footing course supporting a centrally l wall $EFGH$, and if

W = the load of the wall in pounds per linear foot;
w = the width of the wall in feet;
l = the width of the footing in feet;

$\frac{1}{2}(l-w)$ = the projection AE or FB,
$W/l = U$ = the unit load per square foot on the foundation-bed.

...idering the forces acting on the right of the center line of the wall for a ...ngth of wall, it is evident that the uplift on the half-footing OD will equal ...and that its CENTER OF ACTION will lie half-way between O and D, or at a ...ce $\frac{1}{4}l$ from the center line OO; and, similarly, that the load due to one-...the wall will be $\frac{1}{2}W$ and that its CENTER OF ACTION will be at a distance ...from the center line OO. The resulting moments will be

$$M_1 = \tfrac{1}{2}W \times \tfrac{1}{4}l = \tfrac{1}{8}Wl$$

$$M_2 = \tfrac{1}{2}W \times \tfrac{1}{4}w = \tfrac{1}{8}Ww$$

...s these two moments act in opposite directions, the resultant moment ...ing to produce bending in the footing will be the difference between the two, ...e bending moment at the center line OO is

$$M_0 = M_1 - M_2$$

$$M_0 = \tfrac{1}{8}W(l-w)$$

...ince

$$W/l = U \quad \text{and} \quad \tfrac{1}{2}(l-w) = P, \text{ the projection,}$$

...tion (1) may be written in either of the forms

$$\left.\begin{aligned} M_0 &= \tfrac{1}{8}U(l-w)l \\ M_0 &= \tfrac{1}{4}WP \end{aligned}\right\} \qquad (1)$$

...e **Error Involved** in this first method is due to the assumption that the ...re on the upper surface of the footing remains UNIFORMLY DISTRIBUTED, ...the base of the wall acted as a FLUID, in which case the distribution of the ...would remain constant and the formula would be correct. But the base ...e wall is not a FLUID, but a SOLID which will resist DEFORMATION. If, as in ...19, the footing course $ABCD$ deflects and the base of the wall is assumed ...t incompressible, the entire load of the wall will be communicated to the ...ng through the edges E and F. While such a concentration is, of course, ...ible (as the edges E and F will crush or com-... until a considerable area of the base of the ...is in contact with the footing) the result is that ...eight of the wall is concentrated near the outer ...s of its base. Equation (1) gives results which ...oo large; but as it errs on the side of safety, it ...mmended for general use.

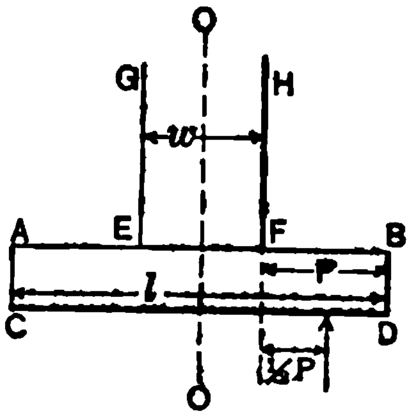

Fig. 23. Bending-stresses in Footings. Second Method

...e **Second Method of Determining Bending-...es in Footings,** also in common use, takes ...nsideration only the projecting portion of the ...g as follows:

...n Fig. 23 $ACBD$ represents a footing course ...ting a centrally located wall $EFGH$, and if ...e the notation of the preceding method, then, if we assume that the ...g acts as a FIXED BEAM and the projections AE and FB as CANTILEVERS ...supported by the wall, and denote the projection of the footing on either

side of the wall by P, the reaction of the foundation-bed on this pr
portion P, per unit length of wall, will be PU. The CENTER OF ACTION
force will be at a distance $\frac{1}{2} P$ from E or F and its moment at E or F

$$M = PU \times \tfrac{1}{2} P = \tfrac{1}{2} UP^2$$

or, since

$$P = \tfrac{1}{2} (l - w)$$

the value of M may be given in the form

$$M = \tfrac{1}{8} U (l - w)^2$$

The Error Involved in this second method is due to the assumption t
uplift on the projection P can be resisted by the extreme outer edge of t
of the wall. If the uplift on the projecting part is concentrated on th
then the edge must either compress or fail by crushing, which, in eith
would throw the center of support for the cantilever back from the edge
wall; and this is contrary to the assumption used in calculating the m
This method takes into consideration only the intensity of the reaction o
and the length of the projection, and is known as the PROJECTION-METHO

Comparison of Results. Comparing the results of the two methods,
be seen that the load cannot act at the two edges E and F as assumed in
tion (2), nor ordinarily can it be uniformly distributed as assumed in E
(1), but that the INTENSITY OF THE LOAD PER UNIT OF AREA will vary,
MINIMUM at the center and a MAXIMUM near the edges of the base of th
The exact positions of the CENTERS OF ACTION are affected by various co
ations which cannot be fully discussed in this chapter.

New Formula for Determining Bending Moments in Footings
writer has devised a formula which gives values for the bending mom
half-way between the values given by Equations (1) and (2), and which
corresponds to the assumption that, considering the forces on either side
center of the wall, the CENTER OF ACTION of the half-load of the wall is
center of the half-wall, when the projection equals zero, and, as the pro
increases, moves toward a position which is two-thirds of the distance fr
center of the wall to its edge. This formula may be expressed as follows:

$$M = \tfrac{1}{8} U (l - w) (l - \tfrac{1}{2} w)$$

Or, substituting the value of U in terms of W,

$$M = \tfrac{1}{8} W (l - w) (1 - w/2l)$$

Weight and Pressure-Units. In practice W, the weight due to the
generally given in pounds per linear foot of wall, and the allowable press
the foundation-bed, while frequently given in tons per square foot, sho
reduced to pounds per square foot.

The Required Width of the Footing in feet is obtained by dividing the
of the wall in pounds per linear foot of wall by the allowable unit load
foundation-bed expressed in pounds per square foot.

Moment-Units. The moment tending to produce rupture may be cal
in foot-pounds or inch-pounds. If in Equations (1), (2) and (3) the dim
l, w and P are in feet and U is in pounds per square foot, the resulting b
moment will be in foot-pounds per linear foot of wall. As the MOMENT OF R
ANCE is generally stated in inch-pounds it is more convenient to have th
IMUM BENDING MOMENT OR MOMENT OF RUPTURE * in inch-pounds. Th
Equation (1)

* In the flexure-formula the moment of resistance is made equal to the
moment at any cross-section of the footing, and the maximum bending mo
sometimes called the moment of rupture.

M (in inch-pounds per foot of wall) = 12 M in foot-pounds,

$$M \text{ (in inch-pounds)} = \tfrac{3}{2}\, U\,(l - w)\, l \qquad (1)'$$

...tion (2) in the same way becomes

$$M \text{ (in inch-pounds)} = \tfrac{3}{2}\, U\,(l - w)^2 \qquad (2)'$$

...ng the more convenient form,

$$M = \tfrac{1}{2}\, UP^2$$

...presses the projection P in inches, instead of in feet, we will have

$$M \text{ (in inch-pounds per foot of wall)} = \tfrac{1}{24}\, UP^2$$

...ly, Equation (3) becomes

$$M \text{ (in inch-pounds per foot of wall)} = \tfrac{3}{2}\, U\,(l - w)\,(l - \tfrac{1}{2} w). \qquad (3)'$$

...il Equations (3) or (3)′ are more generally accepted, an engineer or designer ...ound criticism and be perfectly safe in using Equation (1), and in the follow-...ges the writer will use Equations (1) or (1)′ unless the contrary is stated.

F

l in term of w

Fig. 24. Graphical Comparison of Bending Moments in Footings

...ple. The following is an example illustrating the application of the ...ing formulas:

...-in wall transmits to the footing 42 000 lb per linear foot of wall. The ...ble unit load on the foundation-bed is 3 600 lb per sq ft. What is the ...and required MOMENT OF RESISTANCE * of the footing?

$$42\,000 / 3\,600 = 11\tfrac{2}{3} \text{ ft}$$

* ...the flexure-formula the moment of resistance is made equal to the bending ...at any cross-section of the footing, and the maximum bending moment is ...so called the moment of rupture.

Then, by Equation (1), we have

$$M = \tfrac{1}{8} \times 3\,600\,(11\tfrac{2}{3} - 2)\,11\tfrac{2}{3} = 50\,750 \text{ ft-lb}$$

If Equation (2) is used, we have

$$M = \tfrac{1}{8} \times 3\,600\,(11\tfrac{2}{3} - 2)^2 = 42\,050 \text{ ft-lb}$$

and by Equation (3)

$$M = \tfrac{1}{8} \times 3\,600\,(11\tfrac{2}{3} - 2)\,(11\tfrac{2}{3} - 1) = 46\,400 \text{ ft-lb}$$

Comparing the results we see that the moment by Equation (3) is the
of the moments by Equations (1) and (2).

Graphical Comparison of Bending Moments in Footings. Fig
a graphical comparison of the moments for varying ratios of l to w cal
by Equations (1), (2) and (3) on the assumption that

w = the width of wall = 1 ft;
U = the unit load on the foundation-bed = 1 000 lb per sq ft; a
$r = l/w$.

The load on the wall, in pounds, for any value of l, is 1 000 l.

Comparing the curves of Equations (1) and (2) it will be seen that the
are widely apart, the percentage of variation being highest in the case
projections. When l is less than twice w, or in other words, when the pr
is less than one-half the width of the wall, Equation (2) gives moments le
half the moments given by Equation (1). Equation (2) may be used fo
projections. Equation (1) gives results which are too large, especiall
the projections are small. Equation (3), giving results half-way betwee
of Equations (1) and (2) and in accordance with a reasonable hypothesis
appear to be preferable, but is not in accordance with present practice.

21. Bending Moments in Footings of Columns and Piers

General Statement of the Problem. Fig. 25 represents in plan a
column resting on a footing which projects on four sides. The base
column or pier is represented by $ABCD$, a
footing and its area of support by $EFGH$.
part of the footing included in the areas MN
$QRST$ can be considered as acting in the sa
as projecting footings under a wall, but the u
the four corners $EQMA$, etc., on which no s
posed wall-load is imposed, also causes
moments.

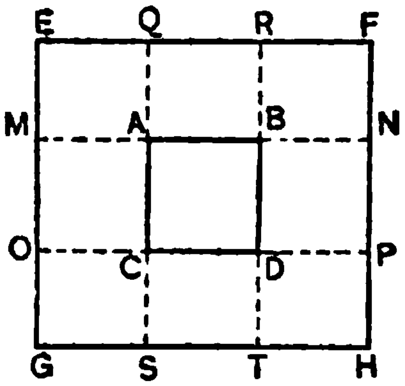

Fig. 25. Plan of Column-footing with Four Equal Projections

Different Theories. There are several t
more or less complicated and unsatisfactory
how the UPLIFT ON THE FOUR CORNER-AREAS
be determined. The discussion of these
would be out of place in this chapter. In a
footing, the projection is not over one-half the width of the superi
base, the four corner-areas will not aggregate over 25% of th
area of the footing, and it may then be assumed that the bending m
is the same as if the base of the column or pier extended like a wall
the entire footing, as is shown in Fig. 26. To insure these conditions, w
projection of the footing exceeds ½ w, and in all cases when the footing
homogeneous, as when a grillage of steel is used, the load of the colum
be distributed over the width of the footing by a GIRDER or BOLSTER o
extension of the column-base. In case the footing is in several layer

must extend the full width of the underlying layer. With such construc- it is evident that the bending moment will be the same as if the GIRDER or ... were a wall and Equation (1) will be applicable.

...ding Moments in Column-Footings. For column-footings Equation ... be used, taking the total load in place of the load per foot, and the result ...then be the total bending ...ent.

...mple. A column carrying ...s is to be supported on a ... concrete slab. The cast- ...column-base is 2 ft square. ...allowable pressure on the ...ation-bed is 6 tons per ... What is the MAXIMUM ...ING MOMENT in the slab? ...he area of support = 96/6 = ... ft = 4 by 4 ft. The pro-

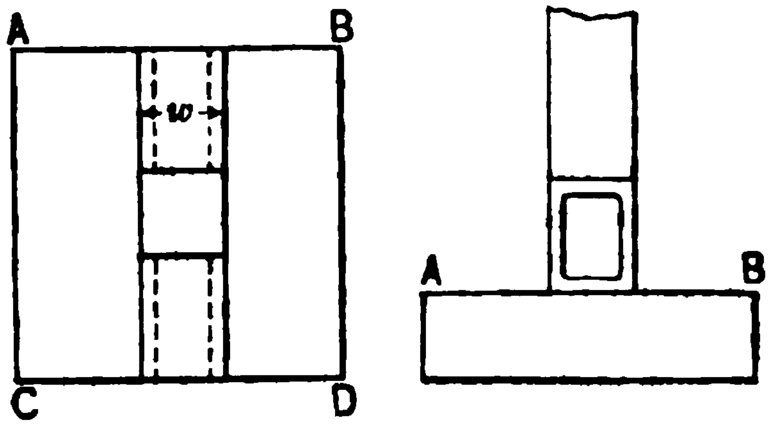

Fig. 26. Column-footing Treated Like Wall-footing

...n is ½ (4 − 2) = 1 ft, or one-half the width of the base, and by the fore- ... rule we can calculate the bending moment as if the base of the column ...ded in one direction across the footing. Applying a convenient form of ...tion (1)

$$M = \tfrac{1}{8} \times 192\,000 \text{ lb } (4 - 2) = 48\,000 \text{ ft-lb, or } 576\,000 \text{ in-lb}$$

...footing must therefore be of sufficient depth to resist this bending ...ent.

...n this example the allowable unit pressure on the foundation-bed is 2 tons ...ad of 6 tons per sq ft the supporting area and the area of the bottom con- ... footing course will be 96/2 = 48 sq ft. If the footing course can be a ...e its dimensions will be, with sufficient exactness, 7 by 7 ft. By the rule ..., since the projection exceeds one-half the width of the base, there should ... BOLSTER extending across the footing. The bolster will be, therefore, 7 ft ...and may properly be composed of two or more steel beams. The cast-iron ...may be dispensed with, in which case the base of the column will be pro- ...d with a steel base or with flange-angles. Let us assume that the column- ...is 1 ft 6 in square and the width of the bolster 2 ft.

...e bending moment in the bolster is determined, then, by Equation (1)· ... 1½ ft, the width of the column-base, for w, and 7 ft, the length of the ...r, for l.

$$M = \tfrac{1}{8} \times 192\,000 \,(7 - 1\tfrac{1}{2}) = 132\,000 \text{ ft-lb} = 1\,584\,000 \text{ in-lb}$$

...bending moment in the slab is determined in the same way by Equation (1), ... 2 ft, the width of the bolster, for w, and 7 ft, the length of the slab, for l.

$$M = \tfrac{1}{8} \times 192\,000 \,(7 - 2) = 120\,000 \text{ ft-lb} = 1\,440\,000 \text{ in-lb.}$$

...tings Other Than Square in Plan. In case it is necessary to use some ... shape than a square for the supporting area the resulting moments in ...slab and bolster will vary from those calculated above. If in the foregoing ...ple the supporting area, for any reason, is necessarily made 6 by 8 ft, giving ... ft as the required area, and if the bolster is parallel with the 6-ft side, the ...ent in the bolster will be

$$M = \tfrac{1}{8} \times 192\,000 \,(6 - 1\tfrac{1}{2}) = 108\,000 \text{ ft-lb} = 1\,296\,000 \text{ in-lb}$$

...he moment in the slab will be

$$M = \tfrac{1}{8} \times 192\,000 \,(8 - 2) = 144\,000 \text{ ft-lb} = 1\,728\,000 \text{ in-lb}$$

or, the moment in the bolster is less and the moment in the slab is grea
in the case of the 7 by 7-ft supporting area. If the bolster runs para
the long side, the moments will be, for the bolster,

$$M = \tfrac{1}{8} \times 192\,000\,(8 - 1\tfrac{1}{2}) = 156\,000 \text{ ft-lb}$$

and for the slab,

$$M = \tfrac{1}{8} \times 192\,000\,(6 - 2) = 96\,000 \text{ ft-lb}$$

In footings having more than two layers, each layer must be inv separately, using l for the length of the layer which is being determine for the width of the superimposed layer.

Compound Footings. In COMPOUND FOOTINGS where, for example and a column or two or more columns are supported by a single foo where loads are cantilevered, the loads will in general be distributed to t porting area by GIRDERS OR CANTILEVERS. The shears and bending m of such girders or cantilevers must be determined for each case by the m used in the calculations of beams and girders in Chapters XV and XX.

22. Design of the Footings

Materials used for Footings. To possess the required strength th MOMENT OF RESISTANCE of the footing must be at least equal to the m OF RUPTURE, calculated as explained in the preceding paragraphs. M whether of brickwork or stone, is not generally suitable for any but th est buildings, as its tensional strength is low. Concrete, plain or rein or grillages of steel embedded in concrete, are generally employed. (See ter III for footings for light buildings.)

Footings of Homogeneous Slabs. If the footing is composed of OF HOMOGENEOUS MATERIAL, as a block of granite or other reliable building or a single layer of concrete, the MOMENT OF RESISTANCE is, by the well- flexure-formula for rectangular cross-sections, $M_r = \tfrac{1}{6}\, bd^2 S$ (see Chapt XV and XVI) in which

d = the depth or thickness of the footing, in inches;
b = the breadth of the footing, in inches;
S = the allowable unit tensile stress of the material, in pounds per inch;
M_r = the moment of resistance.

Placing M, the moment of the forces tending to cause rupture, equal for a length of wall equal to 1 foot we have

$$b = 12 \text{ in}$$

and

$$d^2 = \tfrac{1}{2}\, M/S$$

Substituting in Equation (4) the value for M in inch-pounds as determi formulas (1), (2) and (3) and a value for S as given in the following para the required depth d can be determined.

Safe Tensional Strength for Materials in Footings. The value the ALLOWABLE UNIT TENSILE STRESS, for concrete or stone must include FACTOR OF SAFETY, as experiments show wide variations in the tensional s and in the MODULUS OF RUPTURE OR FLEXURAL STRENGTH of such ma The following values for S in pounds per square inch include a factor of of from 8 to 10 and should not be exceeded. (See, also, Table III, pa Chapter XVI.)

	S in lbs per sq in

...ror in Design of Footings of Several ...s. Equation (2) should not be used where ...oting consists of several layers, as the error ... the erroneous assumption is cumulative and ... result in a serious concentration on the outer ...f the upper layers.

...ple of Footings of Several Layers. In the ...footings cast in separate layers the calculations ... be made as follows: Let l_1 = the length of the footing having a ...t, *M*. From Equation (1), reduced to inch-pounds,

$$l_1 = \frac{2\,M}{3\,W} + w$$

...g decided on the depth of each layer, say 15 in, and a value of *S*, say ...for concrete, then, from the flexure-formula, $M = M_r = \tfrac{1}{6} \times 12 \times 15^2$

$\times$ 35 = 15 750 in-lb, which, substituted in the above equation, will give th of l_1, or the length of the top course. Having determined l_1, the length second course, l_2, is found in the same way, using l_1 for w, and so on u required width of the footing is reached. The dimensions l and w ar taken in feet.

Comparison of Unit and Separate-Layer Footings. Footings i separate layers are very uneconomical in the amount of material require compared with those cast in one operation. If the footing in the p example is designed on the separate-layer basis and the courses assume 15 in thick, their lengths are as follows:

$$l_1 = \frac{2\,M}{3\,W} + w = [(2 \times 15\,750)/(3 \times 28\,000)] + 2 = 2.375 \text{ ft}$$

Also

$$l_2 = 2.75 \text{ ft}, \quad l_3 = 3.125 \text{ ft}, \quad l_4 = 3.50 \text{ ft} \quad \text{and} \quad l_5 = 3.875 \text{ ft}$$

As l_5 is nearly 4 ft, the required length, it may be made so by increas thickness of the bottom course to 16 in. The total thickness of the fo therefore (4 $\times$ 15 in) + 16 in = 76 in instead of 35 in, as previously dete by Equation (1) for the footing cast as a unit.

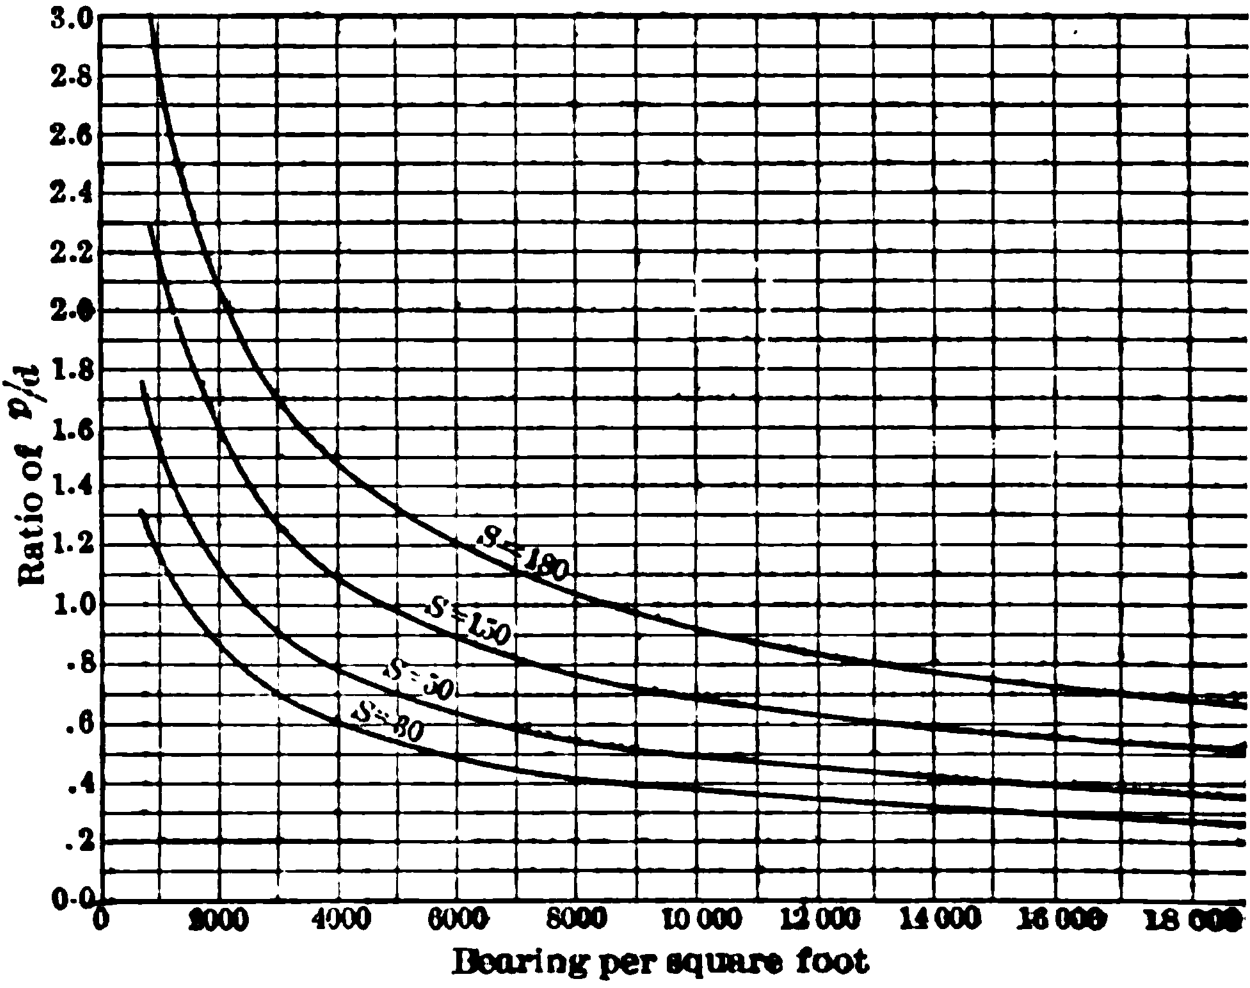

Fig. 28. Diagram Showing Ratio of Projection to Depth of Footings

Rule-of-Thumb Methods for Projections and Steps in Fo Various ARBITRARY RULES are in use which purport to give for different m of construction so-called SAFE PROJECTIONS for given depths of footin give the SAFE RATIO between the projection and the depth of a footing. rules ignore the fact that the uplift varies and they are entirely unreli though such RULES-OF-THUMB are often incorporated in the building c cities. (See Chapter III, page 224.)

Example. The safe projection for offsets in brickwork is frequentl in building codes and in text-books as 3 in for a double course of brick

of about 5 inches, the corresponding ratio being 0.6. If we assume the S for brickwork at 20 lb per sq in, this offset will be safe when the up-than 2 666 lb per sq ft, but not safe when the uplift is over 2 666 lb ft.

of **Projection to Depth of Footing.** For footings of homogeneous however, having a small projection and where Formula (2) can be used it is possible to calculate a so-called SAFE RATIO OF PROJECTION for a unit load. From Equation (2)′ and Equation (4), derived from the for the MOMENT OF RESISTANCE for beams of homogeneous material and cross-section, the following formula may be derived:

$$p/d = \sqrt{48S/U} \qquad (5)$$

all dimensions are in inches, S in pounds per square inch, and U in per square foot. The quantity p/d is the ratio of the projection to the of the beam or footing. For a given value of S the ratio will vary in- as the square root of U.

diagram (Fig. 28) shows curves for different values of S and U from which of projection to depth of footing may be taken. Thus, for a concrete for which the allowable unit stress, S, in tension is, say 30 lb per sq the load, U, on the foundation-bed is 3 000 lb per sq ft, the allowable pro- will be 0.69 times the depth of the footing course. If the concrete is thick, the allowable offset will be 8.3 in. Conversely, for a given offset, in, when the unit load is 3 000 lb and $S = 30$ lb as before, the required will be 1.45 times the offset.

23. Steel Grillages in Foundations*

ntages in the Use of Steel-Beam Grillages. When it is desirable id the deep excavation required for concrete or masonry footings, and the load of a wall has to be distributed over a wide area of support, STEEL or STEEL BEAMS are frequently advantageously used to give the required of resistance with a minimum of depth. Steel beams are generally and preferable to rails, although second-hand rails have frequently been as an expedient.

ring the Bed and Setting the Beams. The foundation-bed should covered with a layer of concrete not less than 6 in in thickness and so and compacted as to be as nearly impervious to moisture as possible. should be placed on this layer, the upper surfaces brought to a line lower flanges carefully grouted so as to secure an even bearing. Sub-ly, concrete should be placed between and around the beams so as to ntly protect them.

irements for Steel Grillages. In determining the number and size beams for any given footing the following points should be considered:

The beams must resist the MAXIMUM BENDING MOMENT, and this without DEFLECTION.

The beams must resist the SHEARING-STRESSES, the meeting of which ent ordinarily provides against CRUSHING.

The beams must not be spaced so far apart that there is danger of the filling between the beams failing to DISTRIBUTE THE LOAD.

The beams must not be spaced so near together as to prevent the placing ete between them. The clear space between the flanges of the top layer preferably be not less than 2 in and should be somewhat more for the yers.

* pages 678 to 680 for an example of a continuous girder in grillage foundation.

(5) Where the BENDING MOMENT is the governing feature, of two equal weight, the deeper beam should be used. Thus, if the required MODULUS is 147, a 20-in 81.4-lb beam might be used; but a 24-in 79-… is stiffer and stronger in bending.

(6) Where the SHEAR is the governing feature, of two beams of equ… the smaller beam is the stronger. Thus, the SHEARING VALUE of a 20… beam is greater than that of a 24-in 80-lb beam and is nearly equivale… of a 24-in 90-lb beam. However, on account of the greater STIFFNE… deeper beam it is sometimes advisable to use it even though the cost is…

Spacing of Beams in Grillage. Table IX gives the LIMITING SP… steel beams, based upon the safe capacity of the concrete filling a… beam, for loads of from 1 to 6 tons per sq ft. Since, however, in s… spans there is considerable ARCHING EFFECT, the concrete will safely… the load on larger spans than those given in the table, provided a… number of tie-rods of proper size are used to take up the THRUST of the…

The Design of a Wall-Footing of steel beams is illustrated by t… ing example: A 24-in wall carries 42 000 lb per lin ft. What should … and spacing of steel beams to distribute the load over the foundati… 3 600 lb per sq ft? The required width of the footing is 42 000/3 60… 8 in and the bending moment by Equation (3) is 556 800 in-lb pe… wall. The amount of shear, by the formula given on page 170, is $S = W$… or 34 800 lb. As the beams are in double shear the single shear per … of wall is 17 400 lb. The required section-modulus per linear foot of … tained by dividing the bending moment by the allowed fiber-stress i… or 556 800/16 000 (assumed fiber-stress) = 34.8. By referring to … page 355, giving the section-moduli of steel beams, we find that a 12… beam has a section-modulus of 36. To satisfy the condition of be… beams must not be spaced more than 36/34.8 = 1.03 ft, center to c… satisfy the condition of web-crippling due to direct compression, the … pressive stress must not exceed the value of S_b, Table II, page 5… for a 12-in 31.8-lb beam, is 13 060 lb per sq in. The area of the bea… compression is the length over which the load is distributed, times … thickness. Some authorities consider that the load is distributed ove…

the loaded portion of the beam plus one-half the depth of the beam, this and the following example the length of only the loaded portion is In this case the area is therefore 24 × 0.35 = 8.4 sq in. If the beams 1.03 ft on centers the unit direct compression is 42 000 × 1.03/8.4 = which is well within the allowed stress given by Table II, page 575. the condition of web-crippling due to shear, the shearing-stress must the value as derived from the formula for allowable shear. (See, XV, paragraphs and foot-notes relating to Buckling of Beam-Webs the illustrative Example 15 in that chapter.) The approximate, allowed, value may be obtained by dividing the value of S_b (Table II, 575) by the factor F, the values of which are given in Table IX A, For example, for a 12-in 31.8-lb beam this shearing value = 13 060/ 7915 lb per sq in. The shearing capacity of the beam is obtained by this unit stress by the depth of beam times the web-thickness, or 12 × 0.35 = 33 240 lb, or much more than required. Only one of the of web-crippling need be considered by applying the following rule: shear divided by the depth of the beam is greater than the total load by the product of the distance (over which the load is distributed) by F, investigate for shear; if otherwise, investigate for direct compres- This rule may also be expressed as follows: According as $(l - w)/l$ is greater than $2D/w'F$, investigate for shear or for compression. Here l = length w = loaded portion of beam, D = depth of beam, w' = length of beam which the load is assumed to be distributed (often taken = $w + \frac{1}{2} D$) and factor for the given beam obtained from Table IX A. All dimensions be taken in the same unit. If, instead of the 12-in beams, 15-in 42.9-lb having a section-modulus of 58.9 are used, the spacing will be 58.9/34.8 ft nearly, say 1 ft 8 in. By referring to Table IX, page 182, it is seen spacing of the beams is well within the safe limit of the concrete and no are theoretically necessary. It is preferable, however, to use at least of tie-rods.

Table IX A. Values of Factor F* for Shearing Values for Various Beams

Beams	For standard-weight beams	For heavy-weight beams
12-in beam	1.65	1.52
15-in beam	1.71	1.50
18-in beam	1.76	1.58
20-in beam	1.77	1.62
24-in beam	1.91	1.67

factors, F, which have been deduced to be used in connection with S_b, Table II, 574-5, to give the safe unit shearing value based on web-crippling, will help greatly computations of shears in case tables of safe shears are not obtainable. It is to be however, that the values derived from the use of F are approximate only, as this a little different for every beam; and to give its value for every beam would as much space as complete tables of safe shears. The values of F are not given sections of light beams as they are not usually good sections for grillages. be mentioned that the standard weight for each size of beam for which F is given the next weight higher than the minimum weight given in Table II, pages 574-5, the 20-in beams, for which the minimum weight, 65.4 lb, is also the standard. The rule given above for determining whether web-crippling based on shear or compression is the determining condition eliminates one of the calculations to in investigating grillages.

The Design of a Column-Footing of steel beams is illustrated following example: A column carries 576 tons. The allowable pressure foundation-bed is 3 tons per sq ft. What should be the arrangement, and size of the steel beams composing the grillage? The required area port = 576/3 = 192 sq ft. In order to make the problem as general as let it be supposed that practical considerations limit the width of the fo 12 ft. The dimensions of the concrete mat on which the lower layer of rests will be 12 by 16 ft. By referring to the diagram (Fig. 28) we find the mat is made 12 in thick an offset of 6 in is permissible. The dim of the lower layer of beams will therefore be 11 by 15 ft. A suitable gril the given conditions may be designed of two or of three layers. If tw are used the length of the top beams will be 11 ft. Assuming the colu = 30 in, the loaded portion = 2½ ft, and by Formula (1), the bending m = ¼ × 1 152 000 lb × (11 − 2½) × 12 × ½ = 14 688 000 in-lb, from wh required section-modulus (at 16 000-lb maximum fiber-stress) = 918. ferring to Table IV, Chapter X, five 24-in 90-lb beams have a section-m of 929 and consequently satisfy the condition of bending. By apply rule given in the preceding paragraph for the design of a wall-footing, web-crippling due to shear or to compression is to be investigated, $(l -$ 0.773 and $2\ D/w'F$ = 0.958, which, being greater than 0.773, shows that th should be investigated for web-crippling due to compression, by the explained in the previous example. It will be found that the five 24- beams also satisfy this condition and will therefore be used. Their width is about 7⅛ in, so they should be spaced about 9¼ in on centers ing the length of the column-base to be about 3 ft 9 in. The calcula the lower layer is similar, the length of the beams being 15 ft and the portion, 3 ft 9 in. It is rarely necessary to investigate the lower layer crippling, the condition of bending, except for the top layer, being usu governing feature. If, owing to conditions of bending, it is not practi make the beams of the top layer sufficiently long to extend across the width of the concrete mat, it is then necessary to make the grillage layers. The calculation for a three-layer grillage for the same problem preceding is as follows:

Calculation of the Top Layer. For web-crippling due to comp 1 152 000 lb = $S_b \times w' \times t \times n$, where S_b = the allowable unit stress, length of beam over which the load is assumed to be distributed, t = t thickness and n = the number of beams. Referring to Table II, Chap and assuming a 20-in 75-lb beam to be used, S_b = 13 660 lb per sq in 0.641 in. Taking w' = 30 in (the width of the column-base), 13 660 0.641 = 262 682 lb and the value for five beams is 1 313 410 lb, which than enough. But it is found that five 20-in 70-lb beams would not cient. It will be economical to make these beams of the greatest length f they will resist bending. The section-modulus of one beam is 126.3; total M_r = 5 × 126.3 × 16 000 (assumed fiber-stress). This may be dete also, by Formula (1) in which $M = \frac{1}{4}\,WP$. From these equations th tion P = 35¼ in, and the length of the beams is therefore (2 × 35¼) + width of the base) = 100½ in, or approximately 8 ft 4 in. By appl foregoing rule to see if web-crippling due to shear must be co (100 − 30)/100 = 0.7 which is less than 40/(30 × 1.62) = 0.82, and t need not be investigated.

* It is to be noted that the bending moment is the same as for a beam uniform with 576 tons on a span of 8½ ft, $(l - w)$, and that the number and size of the beams, as far as bending is concerned, may be taken from the tables giving the of beams. See Table IV, Chapter XV.

width of the flanges of these beams is nearly 6¼ in, so that they should be from 8½ to 9 in, thus making the required length of column-base 5 ft 6 in.

...ion of the Second Layer. Since the length of the top layer is limited ...4 in and the width of the lowest layer is 11 ft, it will be necessary to have ...mediate layer. This ...er the area given by ...gth of beams of the top ...and the width of the ...layer, or 8 ft 4 in by 11 ...he beams will of course ...right-angles to those of ...p layer, so their length ...11 ft, and they are to ...paced as not to exceed ...in. Since the width of ...course is 3½ ft, their ...is (11 ft − 3½ ft)/2 ...ft, the amount of single ...1 152 000 × 3.75/11 = ...lb and the bending ...is ½ × 1 152 000 × 45 ...960 000 in-lb. Using ...lb as the fiber-stress the ...section-modulus is ...by referring to Table ...apter X, for section- ...and determining the ...m shear as above ex- ..., we find that ten 15-in ...beams will have a total ...modulus of 812, and ...all also be ample for ... Furthermore, ten ...paced to cover a width ...in will give a spacing, ...to center of beams, of ...in, which is sufficient. ...ll be better, however, ...n 18-in 54.7-lb beams.

...tion of the Bottom ... Taking the effective ...f the middle layer as ...he projection of the ...(15 ft − 8 ft)/2 = 3½ ...n similarly to the ...he shear = 268 800 lb. ...2 096 000 in-lb, from ...the section-modulus = 756, and thirteen 15-in 42.9-lb beams, spaced 10½ ...ters, will be required, or two 15-in 60.8-lb beams and ten 15-in 42.9-lb ...ay be used, increasing the spacing between the beams. In this case ...y beams should be placed nearest to the center of the footing. This ...illustrated in Fig. 29.

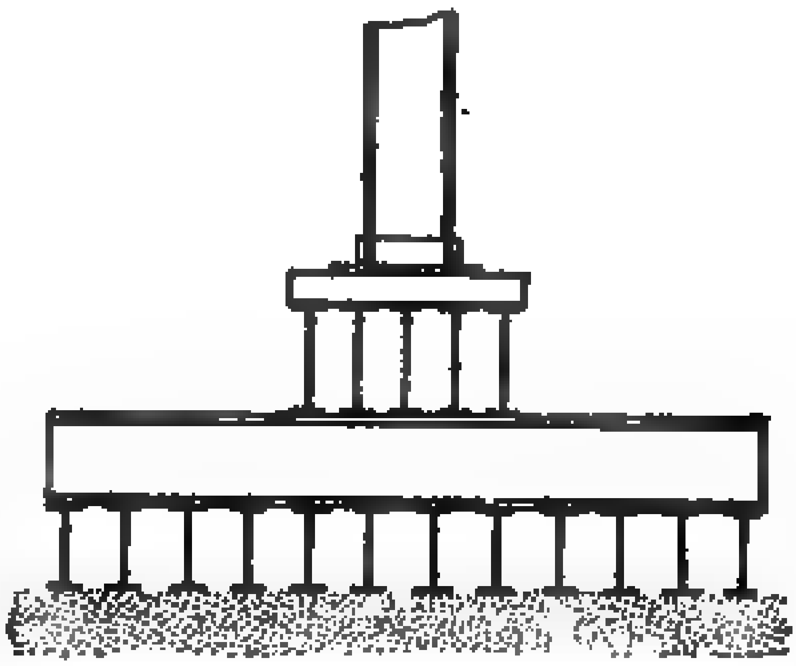

Fig. 29. Steel-beam Grillage Column-footing

24. Reinforced-Concrete Footings

Advantages and Disadvantages. Reinforced concrete has in recen been largely used for footings. The arguments in favor of its use are:

(1) Low cost of the footing-construction;

(2) Reduction in the amount of excavation required,

(3) Convenience, as compared with the use of steel-beam grillages, the reinforcing-steel is readily obtainable, can be cut to length on the w handled without derricks.

The objections urged are:

(1) Danger of defective workmanship, as the strength of the footing upon the proper mixing and placing of the concrete, the proper placin reinforcement and the complete union of the concrete with the reinfor The danger of defective workmanship is increased by reason of the usual ties of foundation-work, in that water and mud are generally present difficulty of careful work and inspection is greater.

(2) Danger of the deterioration of the steel reinforcement either by or by electrolysis. This danger is increased by the presence of moisture the relatively small cross-section of the reinforcing-bars. In this con it is well to remember that in reinforced-concrete girders as usually the concrete on the tension side is stressed beyond its elastic limit, as a which, numerous fine cracks are developed under the figured load.

Use of Reinforced Concrete for Foundations. From the foregoi apparent that great care should be used in connection with reinforced in foundations, especially as any defect is difficult to detect or repair. forced concrete is used not only for so-called MATS or SLABS but is fre used for DISTRIBUTING-GIRDERS, BOLSTERS and even for CANTILEVER author's preference is against reinforced concrete for foundations for im structures.

The Methods Used in Calculating the Strength of Reinforce crete Slabs, Girders, etc., are explained in Chapters XXIV and XX stresses coming on the reinforced-concrete construction are to be det in the same way as explained for footings of other materials.

25. Timber Footings for Temporary Buildings

Timber Footings. For buildings of moderate height timber may to give the necessary spread to the footings, provided water is always The footings should be built by covering the bottom of the trenche should be perfectly level, with 2-in planks laid close together and longit with the wall. Across these planks heavy timbers should be laid, spac 12 in on centers, the size of the timbers being proportioned to the tr stress. On top of these timbers again should be spiked a floor of 3-i of the same width as the masonry footings which are laid upon it. A of such a footing is shown in Fig. 30. All of the timber-work must below low-water mark, and the space between the transverse timbers s filled with sand, broken stone, or concrete. The best woods for such tions are oak, long-leaf yellow pine and Norway pine. Many of the o ings in Chicago rest on timber footings.

Calculations for the Sizes of the Cross-Timbers. The sizes of t verse timbers should be computed by the following formula:

$$\text{Breadth in inches} = \frac{2 \times w \times p^2 \times s}{d^2 \times A},$$

ing the bearing resistance of the foundation-bed in pounds per square the projection of the transverse timbers beyond the 3-in planks, in feet, nce on centers of the timbers in feet, and d the assumed depth of the n inches. A is the constant for strength.* The values recommended for for long-leaf yellow pine and white oak, 44 for Norway pine, and 39 for white pine or spruce, all increased from 30 to 40% for temporary build- (See Table II, page 628.)

Fig. 30. Spread Footing of Timber

ple. The side walls of a given building impose on the foundation a of 10 000 lb per lin ft; the soil will only support, without excessive nt, 2 000 lb per sq ft. It is decided for economy to build the footings as in Fig. 30, using long-leaf yellow-pine timber. What should be the size nsverse timbers?

n. Dividing the total pressure per linear foot by 2 000 lb, we have the width of the footings. The masonry footing we will make of granite hard stone, 4 ft wide, and solidly bedded on the planks in Portland, mortar. The projection p of the transverse beams will then be 3 ft. pace the beams 12 in on centers, so that $s = 1$, and will assume 10 in depth of the beams. Then, by the formula,

$$\text{the breadth in inches} = \frac{2 \times 2000 \times 9 \times 1}{100 \times 90} = 4 \text{ in}$$

hould use 4- by 10-in timbers, spaced 12 in on centers. If spruce timber d we should substitute 55 for 90, and the result would be 6½ in. (See p 628, for A increased from 30 to 40%.)

ations for Temporary Buildings. When temporary buildings are lt on a compressible soil, the foundations may, in some parts of the be constructed more cheaply of timber than of any other material, and ases the durability of the timber need not be considered, as when it is will last two or three years in almost any place, if thorough ventilation ed. The World's Fair buildings at Chicago (1893) were, as a rule, d on timber platforms, proportioned so that the maximum load on the d not exceed 1¼ tons per sq ft. Only in a few places over MUD-HOLES foundations used.

lues given to the term A of the formula vary in different building codes.

26. General Conditions Affecting Foundations and Footin

General Considerations. Where the footings of a building rest on w or on clay, it is important that any movement of the material forn foundation-bed be prevented if possible. In many cases it is advisable nect all footings with a concrete floor to prevent any UPLIFT of the fou bed between the footings. Where unequal settlement is apprehend inadvisable to have long columns firmly attached to the footings, as any settlement of the footings develops a BENDING-STRESS in the colum bending-stresses, in the case of long columns, may become extremely resulting possibly in the rupture or distortion of the columns. In such has even been proposed to design the bases of the columns with BALL-ANI joints which would allow unequal settlement of the footings without d or bending of the columns. Such connections, however, could not be g used because of the necessity of bracing the structure against the h pressure of the wind, but they would be entirely practicable in the cas interior columns.

The Minimum Depth of Footings is limited by the depth of th by the requirements of the cellar as to whether part of the footings car above the cellar-floor level, and by the depth of the footing itself. The n depth will be advantageously exceeded if, by a slight increase in depth, a capable of sustaining a higher unit load is found on which to rest the or if, as explained in previous articles of this chapter, greater security is by locating the footing at a greater depth. These considerations will the design of a footing and in all cases should be taken into considerat some cases it may be cheaper to abandon the use of a SPREAD FOOTING of and resort to PILES or MASONRY CONSTRUCTION going to ROCK or to so solid substratum. Where there is any question on this point, careful co should be made of the advantages and costs of the two methods. In however, it will be cheaper to spread footings immediately below th excavation level than to employ any of the various deep-foundation me

Deep Foundations are necessary when the material at the level SPREAD FOOTINGS would ordinarily be constructed is not suitable, or i is desirable for any reason to carry the foundations of the building do underlying stratum of greater supporting power. Recourse must the to one or more of the following expedients:

(1) Wooden piles;
(2) Concrete piles;
(3) Piers or walls constructed in pits or trenches, or by other meth going down to the required depth to reach a solid stratum.

27. Wooden-Pile Foundations

The Use of Wooden Piles. When it is required to build upon a sible soil that is constantly saturated with water and of considerable d most practicable method of obtaining a solid and enduring found buildings of moderate height is by driving wooden piles. Many bu the city of Boston, Mass., and several tall office-buildings of New Y and Chicago, rest on wooden piles, and they are extensively used for s buildings, grain-elevators, etc., erected along the water-front of coast cities. The durability of wooden piles in ground constantly satur water is beyond question, as they have been found in a perfectly sou tion after the lapse of from six to seventeen centuries.

nicipal Requirements. The laws of Boston require that wooden piles be capped with block-granite levelers or with Portland-cement concrete, that the spacing shall not exceed 3 ft between centers. The laws of Chicago are that wooden piles shall be driven to rock or hard-pan and capped with ge of timber, concrete, or steel, or a combination of these. The laws of York specify a minimum diameter of 5 inches and a maximum spacing of t between centers.

e Maximum Loads Allowed on Wooden Piles in various cities are as s: Atlanta, 20 tons; Philadelphia, 20 tons; Buffalo, 25 tons; Minneapolis, ns; Richmond, 25 tons; St. Louis, as many tons as the piles will safely t; Chicago, 25 tons; Louisville, 20 tons; St. Paul, 25 tons; New York, ns; Portland, Ore., 25 tons; Cleveland, 25 tons. Most of the above cities t the allowed load by Wellington's formula which is hereinafter given ge 193, under the heading, Bearing-Power of Piles.

nds of Wood Used for Piles. Wooden piles are made from the trunks es and should be as straight as possible and not less than 5 in in diameter e small end for light buildings, or 8 in for heavy buildings. The woods ally used for piles are spruce, hemlock, white pine, Norway pine, long-leaf short-leaf yellow pine, pitch-pine, cypress, Douglas fir, and occasionally oak, ry, elm, black gum and basswood. There does not appear to be much ence in the woods as to ility under water, but the er and stronger woods are preferred, especially where piles are to be driven to pan and heavily loaded.

eparing Wooden Piles Driving. The piles should REPARED FOR DRIVING by g off all limbs close to the t and sawing the ends e. It is probably better move the bark, although are more often driven with ark on, and it is doubtful if rk makes much difference ay or the other. For g in soft and silty soils, ence has shown that the drive better with a square t. When the penetration is han 6 in at each blow the f the pile should be pro- from BROOMING by put- ne IRON RING, about 1 in diameter than the head of e and from 2½ to 3 in y ¾ in thick. The head should be chamfered to fit the ring. When into compact soil, such as sand, gravel, or stiff clay, the point of e should be SHOD with iron or steel. The method shown at *A*, Fig. 31, s very well for all but very hard soils, and for these a CAST CONICAL POINT 5 in in diameter, secured by a long DOWEL, with a RING around the end pile, as shown at *B*, makes the best shoe. Piles that are to be driven in or

Fig. 31. Points of Wooden Piles Prepared for Driving

exposed to salt water should be thoroughly impregnated with creosote, d
or coal-tar, or some mineral poison to protect them from the TEREDO o
WORM, which will completely honeycomb an ordinary pile in three or fou

Driving Wooden Piles with the Drop-Hammer. The piles should
be driven to an even bearing, which is determined by the PENETRATIO
the last four or five blows of the hammer. The usual method of drivi
for the support of buildings is by a succession of blows given with a b
cast iron or steel, called the HAMMER, which slides up and down betw
uprights of a machine called a PILE-DRIVER. The machine is placed o
pile, so that the hammer descends fairly on its head, the piles alway
driven with the small end down. The hammer is generally raised by stean
and is dropped either automatically or by hand. The usual weight
hammers used for driving piles for building foundations is from 1 500 to 2
and the fall varies from 5 to 20 ft, the last blows being given with a sh
Occasionally, hammers weighing up to 4 000 pounds and over are used.

Driving Wooden Piles with the Steam-Hammer. Steam-ha
are to a considerable extent taking the place of the ordinary drop-ham
large cities, as they will drive many more piles in a day, and with less
to the piles. The steam-hammer delivers short, quick blows, from s
seventy to the minute, and seems to jar the piles down, the short inte
tween the blows not giving time for the soil to settle around them.† I
ing piles care should be taken to keep them plumb, and when the pen
becomes small, the fall should be reduced to about 5 ft, the blows being
rapid succession. Whenever a pile refuses to sink under several blows
reaching the average depth, it should be cut off and another pile driven b
When several piles have been driven to a depth of 20 ft or more and r
sink more than ½ in under five blows of a 1 200-pound hammer falling
is useless to try them further, as the additional blows only result in b
and crushing the heads and points of the piles, and splitting and crus
intermediate portions to an unknown extent.

Spacing Wooden Piles. Piles should be spaced not less than 2 ft n
than 3 ft, on centers, unless iron, wooden, or reinforced-concrete gr
used. When long piles are driven closer than 2 ft on centers there is dan
they may force each other up from their solid bed on the bearing s
Driving the piles close together also breaks up the ground and dimini
bearing power. When three rows of piles are used the most satisfacto
ing is 2 ft 6 in on centers across the trench and 3 ft on centers longitu
provided this number of piles will carry the weight of the building.
will not, then the piles must be spaced closer together longitudinally, or
row of piles driven; but in no case should the piles be less than 2 ft
centers, unless driven by means of a water-jet. The number of piles u
different portions of the building should be proportioned to the weigh
they are to support, so that each pile will receive very nearly the same l

Capping Wooden Piles. The tops of the piles should invariably
off at or a little below low water-mark, otherwise they will soon comm
decay. They should then be capped, either with large stone blocks, or
or with timber or steel grillage.

Granite Capping. Wooden piles are sometimes capped with bloc
LEVELERS which rest directly on the tops of the piles. If the stone do

* See Table XI, page 204.

† The 5 000 piles, averaging 48 ft in net length, under the Chicago Post O
driven with a steam-hammer weighing 4 400 lb and delivering 60 blows per mi

...of the pile, or a pile is a little low, it is wedged up with oak or stone ... In capping with stone a section of the foundation should be laid out ... drawings showing the arrangement of the capping stones. A single ... may rest on one, two, or three, but not on four piles, nor on three piles in ... line, as in the two last-mentioned ... it is practically impossible to make the ... bear evenly. Fig. 32 shows the best ... of the capping for three rows of ... Under dwellings and light buildings the ... often driven in two rows, STAGGERED, in ... case each stone should rest on three piles. ... the piles are capped, large footing stones, ... in single pieces across the wall, should ... in cement mortar on the capping. Fig. ... a partial piling-plan, with the arrange... of the capping stones, of the Boston ... of Commerce Building. It may be ... most of the stones rest on three piles, ... few on two piles.

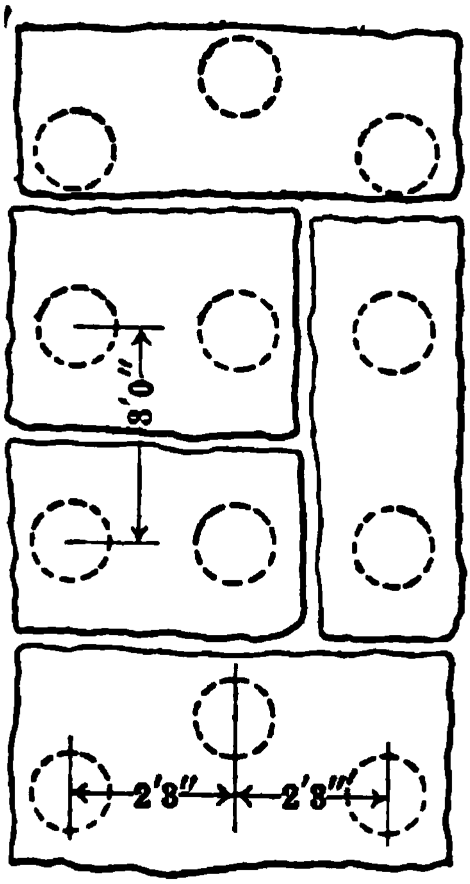

Fig. 32. Stone Capping for Three Rows of Wooden Piles

... Capping. In many buildings a very ... method of capping is to excavate to a ... of 1 ft below the tops of the piles and 1 ft ... of them and to fill the space thus ... solid with Portland-cement concrete, ... in layers and well rammed. After the ... is brought level with the tops of the ... additional layers are deposited over the ... width of the foundation until the concrete ... a depth of 18 in above the piles. On this foundation brick or stone ... are laid as on solid earth. If long bars of twisted steel, about ¾ in ... in cross-section are embedded in the concrete about 3 in above the ... the piles, the construction makes, in the opinion of the author, the best ... capping, the twisted bars giving great transverse strength to the concrete.

...-Grillage Capping. The pile foundations of many buildings have ... timber grillages bolted to the tops of the piles and stone or concrete foot... on top of the grillages. The timbers for the grillages should be at least ... in in cross-section, and should have sufficient transverse strength to ... the load from center to center of piles, using a low fiber-stress. They ... laid longitudinally on top of the piles and fastened to them by means ... -BOLTS, which are plain bars of iron, either round or square in section, ... into holes about 20% smaller in section than the bolts themselves ... or square bars 1 in in section are generally used, the holes being bored ... auger for the round bolts and by a ⅞-in auger for the square bolts. ... should enter the piles at least 1 ft. If heavy stone or concrete footings ... and the space between the piles and timbers is filled with concrete level ... tops of the timbers, no more timbering is required; but if the footings ... of small stones and no concrete is used, a solid floor of cross-timbers, ... 6 in thick for heavy buildings, should be laid on top of the longitudinal ... and drift-bolted to them. Where timber grillage is used it should, of ... be kept entirely below the lowest recorded water-line, as otherwise it ... and allow the building to settle. It has been proved conclusively, ... that any kind of sound timber will last practically forever if completely ... in water.

The Advantages of Timber Grillage are that it is easily laid and effe holds the tops of the piles in place. It also tends to distribute the p evenly over the piles, as the transverse strength of the timber will help t

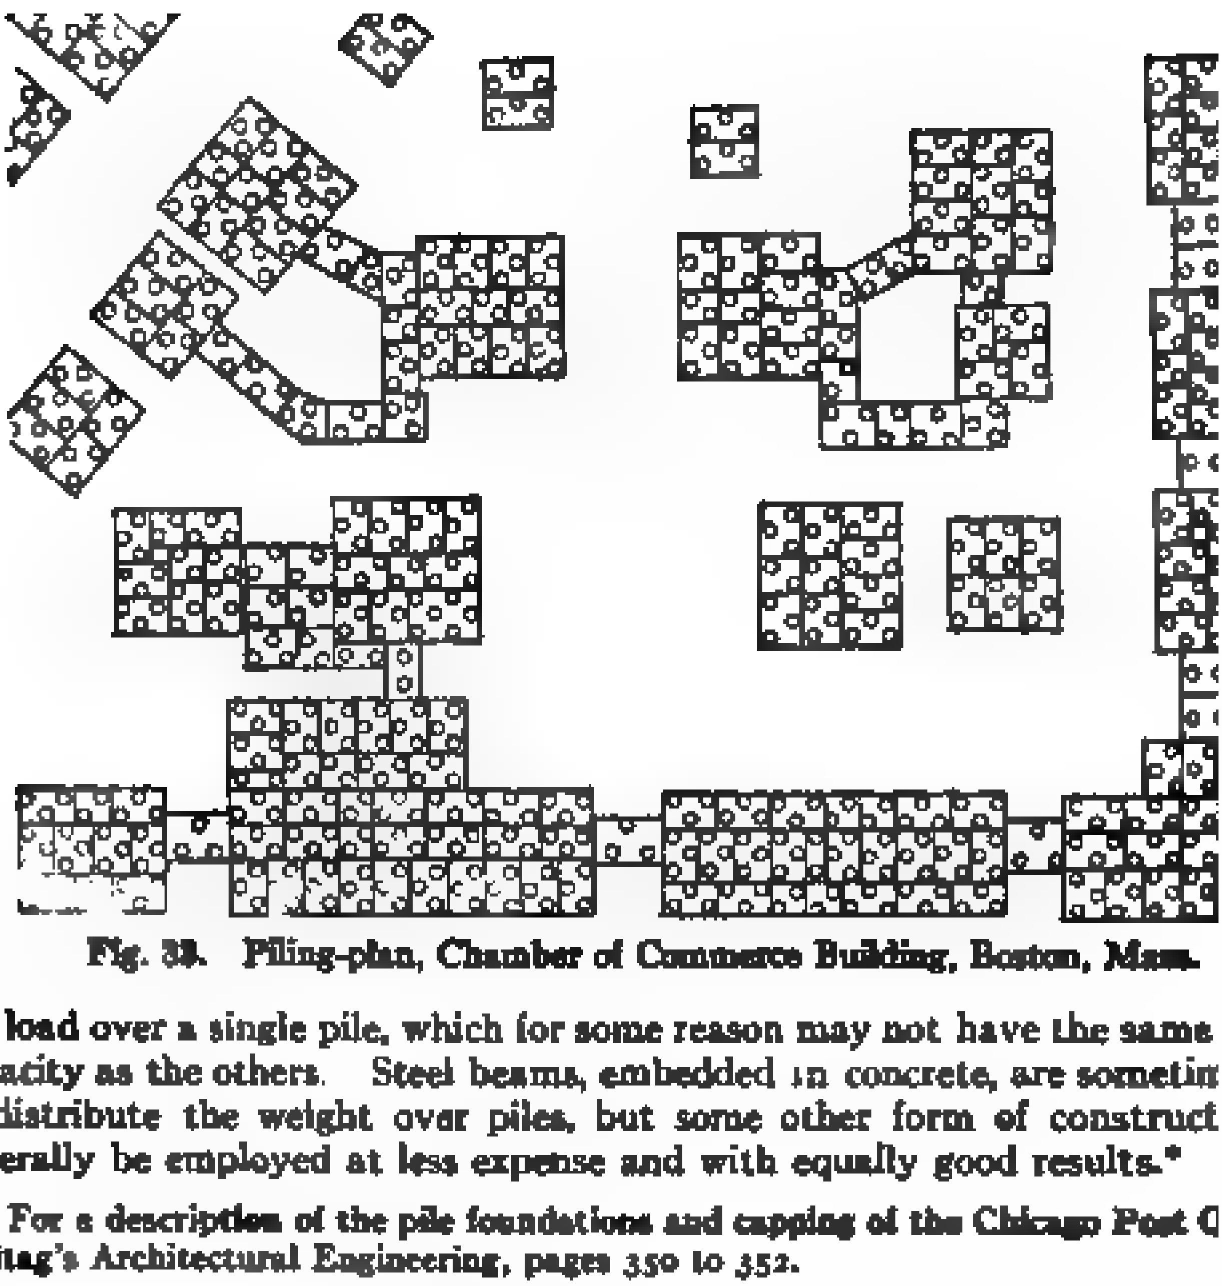

Fig. 39. Piling-plan, Chamber of Commerce Building, Boston, Mass.

the load over a single pile, which for some reason may not have the same capacity as the others. Steel beams, embedded in concrete, are sometim to distribute the weight over piles, but some other form of construct generally be employed at less expense and with equally good results.*

...y are to be not less than 6 in in diameter at the small end, 10 in at the ...end, when cut off, and of sufficient length to reach solid bottom, the neces... ...length of piles to be determined by driving test-piles in different parts of ...undation.

...piles are to be driven vertically, in the exact positions shown by the plan, ...they do not move more than 5 in under the last five blows of a hammer ...ing 2000 lb and falling 20 ft. All split or shattered piles are to be re... ...d if possible and a good one driven in place of each imperfect one. In ...where such piles cannot be removed an additional pile is to be driven for ...imperfect one. If the piles show a tendency to BROOM, they are to be ...d with wrought-iron rings, 2½ in wide and ½ in thick.

...piles, when driven to the required depth, are to be sawed off square for a ...ental bearing at the grade indicated on the drawings.

...Bearing Power of Piles. In regard to their use for supporting build... ...piles may be divided into two classes: (1) Those which are driven to ...or HARD-PAN, that is, firm GRAVEL or CLAY and (2) those which do not ...HARD-PAN.

...A pile belonging to this class when driven through a soil that is sufficiently ...to brace the pile at every point, may be computed to sustain a load equal ...safe resistance to crushing on the least cross-section. If the surrounding ...plastic the bearing power of the pile will be its safe load computed as a ...n, having a length equal to the length of the pile when capped. Test... ...driven on the site of the Chicago Public Library Building, through 27 ft ...l, plastic clay, 23 ft of tough, compact clay and 2 ft into hard-pan, sus... ...d a load of 50.7 tons per pile for two weeks without apparent settlement. ...are many instances where piles driven to the depth of 20 ft in hard clay ...n from 20 to 40 tons, and a few instances where they sustain up to 80 tons ...e.

...A pile belonging to this class depends for its bearing power upon the ...ss, COHESION and BUOYANCY of the soil into which it is driven. The ...load for such piles is usually determined by the average penetration of ...e under the last four or five blows of the hammer. Several engineers ...formulated rules for determining the safe loads for piles of this class, but ...are so many conditions that modify the amount of the penetration, and ...act determination, and so many varying conditions of driving and of ...that it is considered impossible to formulate any rule that can be considered ...y satisfactory for all the conditions under which such piles are driven.

...Engineering News Formula. The formula generally used by engineers ...rived by M. A. Wellington, and is often referred to as the ENGINEERING ...FORMULA:

$$\text{The safe load in tons} = 2\,wh/\,(S+1)$$

...ich

w = the weight of the hammer in tons;
h = the height of fall of the hammer in feet;
S = the penetration in inches under the last blow or the average under the last five blows.

...loads are based on this formula the piles should be driven until the pene... ...does not exceed the limit assumed, or if this is found to be impracticable,

new calculations must be made based on the smallest average penetrati
can be obtained, and a greater number of piles used. In localities wher
is commonly used for foundations, the least penetration that can be ol
within practical limits of length of pile can generally be ascertained by o
tion, or by consulting somebody who is experienced in driving piles. The
the pile the less, as a rule, will be the final SET or penetration. Where the
experience to guide one it will be necessary to drive a few piles to det
the length of pile required, or the least SET for a given length of pile.
piles will have to be driven further than others to bring them to bear
equal resistance. When the piles are to be loaded to more than 50%
assumed safe load, the final set of each pile should be carefully measurec
inspector, the BROOM and SPLINTERS being removed from the head of t
for the last blow.

Safe Loads for Piles. Table X, computed by the above formula, gi
safe loads for different penetrations, under different falls of a hammer w
1 ton. FOR A HAMMER OF DIFFERENT WEIGHT multiply the safe load in tl
by the actual weight of the hammer in tons. Thus, for a hammer w
1 000 lb, the values in the table should be multiplied by ½ and for a :
hammer, by ¾.

Table X. Safe Loads in Tons for Piles

For hammer weighing 1 ton

Penetration of pile in inches	Height of the fall of the hammer in feet

Example of Computations for Pile Foundation. Suppose that fr
observations of the pile-driving for an adjacent building it is found tl
driven from 20 to 30 ft take a set of 1 in under a 1 200-lb hammer fallin
and that additional blows result in about the same set.

From Table X we find that the safe load for a fall of 20 ft and a p
tion of 1 in is 20 tons. Multiplying by the weight of the hammer in t
we have 12 tons as the safe load per pile. Suppose that the total lo
lin ft of footing is 13 tons. As we must have at least two rows of pi
each two piles will support 24 tons, it follows that the spacing of t
longitudinally should be 24/13 = 1 ft 10 in. As this is too close, we sh
three rows of piles, spaced 2 ft apart laterally, and the longitudinal

then be 36/13 = 2 ft 9 in. The width of the capping would be about If the load on the piles under the interior columns, for example, is 105.8 this divided by 12, the safe load for one pile, gives nine piles, or three rows he piles each, which should be spaced 2 ft 6 in apart, each way.

Actual Loads on Wooden Piles. The following examples of the loads supported by piles, under well-known buildings, and of loads which have borne for a short time without settlement, should be of value when ing pile foundations.

...ON. At the Southern Railroad Station three piles were loaded with 60 tons of pig iron, 20 tons per pile, without settlement. The allowed was 10 tons per pile.

...s 12 in in diameter at the butt and 6 in at the point, driven 31 ft into hard, clay near Haymarket Square, failed to show movement under 30 tons, ultimate load being probably 60 tons.* Other piles driven 17.9 ft sustained of 31 tons each. The average penetration under the last ten blows of a lb hammer falling from 9 to 12 ft varied from 0.4 to 0.95 in per blow for piles.

...s 25 ft long under the Chamber of Commerce Building penetrated about under the last blow of a 2 000-lb hammer falling about 15 ft.

...CAGO. In the Public Library Building the piles were proportioned to ns each and were tested to 50.7 tons without settlement.

...the Schiller Building the estimated load was 55 tons per pile; the building d from 1½ to 2¼ in.

...the Passenger Station of the Northern Pacific Railroad, at Harrison Street, 50 ft long were designed to carry 25 tons each and did so without per-...le settlement.

...e Art Institute Building, parts of the Stock Exchange Building and also e number of warehouses and other buildings on the banks of the river n piles.

...W YORK CITY. The Ivins (Park Row) Building is supported by about 14-in spruce piles, arranged in clusters of fifty or sixty, for single columns, a corresponding number under piers supporting two or more columns. ...les were driven to refusal of 1 in under a 20-ft fall of a 2 000-lb hammer. ...terial is fine, dense sand to a depth of over 90 ft. But few piles could be t more than 15 or 20 ft. The average maximum load per pile is 9 tons.† ...e American Tract Society's Building is supported on piles.

...OKLYN. Piles under the Government Graving Dock, driven 32 ft, on ...rage, into fine sand mixed with fine mica and a little vegetable loam, are ...ed to sustain from 10 to 15 tons each.

...W ORLEANS. Piles driven from 25 to 40 ft into a soft alluvial soil carry from 15 to 25 tons, with a factor of safety of from 6 to 8.‡

Cost of Driving Wooden Piles.§ The cost of driving piles naturally varies ...he character of the soil, and the conditions under which they are driven.

...W YORK CITY. A 2 500-lb drop-hammer drove 4 piles per day of 10 hours. ...steam-hammer, 13 piles per day were driven, for the same foundation. ...les were 70 ft long, 8 in in diam at the point and 15 in at the head. ...average cost of driving 800 piles with the steam-hammer was $2 each. In ...ark Harbor 1 800 piles were driven by a steam-hammer, from 24 to 26 ft ...vel and hard-pan, at a cost of 80 cts each.

...J. Howe, American Architect, June 11, 1898.

...a description of this foundation, see the Engineering Record of July 23, 1898.

...L. Patton.

...e prices are now (1920) considerably higher.

CHICAGO. Forty Norway-pine piles were driven by a firm of contr 15 ft deep every ten hours at a cost, for driving, of 55 cts each. Anoth drove from 60 to 65 piles, each 45 ft long and 15 ft deep, into hard sand ea at a cost of about 30 cts each. In both cases steam-hammers were used.*

BOSTON. Spruce piles from 30 to 45 ft long cost from \$3 to \$5, in Long-leaf yellow pine piles, as long as 70 ft, cost about \$15 apiece for th themselves, and \$2 or more each for the driving. Oak piles from 40 to long cost from \$8 to \$10 each, in place.†

Some Other References to Wooden Piles and Pile-Driving. A valuable paper on "Some Instances of Piles and Pile-Driving, New and by Horace J. Howe, was published in the American Architect and Building commencing June 11, 1898. The paper records a great many tests and several formulas and many experiences of distinguished engineers. Pa Building Construction and Superintendence, by F. E. Kidder, gives add information in regard to pile foundations and experiments on the bearing of piles. Much valuable information on piles is given in "A Practical T on Foundations," by W. M. Patton. The recent Engineers' Handbook should be consulted for additional data.

28. Concrete-Pile Foundations

Durability of Wooden and Concrete Piles. Concrete piles, either or reinforced, possess many advantages over wooden piles and, in gener be used in all places where wooden piles can be driven. Concrete piles pared with wooden piles, have primarily the advantage of greater PERMA Timber piles, kept constantly wet and protected from the action of the or other destructive influences, may be practically everlasting, but can counted upon above water level; whereas concrete piles should be proof all deteriorating actions, whether wet or dry, except the action of free wet concrete.

Strength of Wooden and Concrete Piles. Concrete piles withou forcement, if made of good concrete, should have nearly the same CR STRENGTH per square inch as ordinary yellow-pine piles, and with p placed reinforcement concrete piles should have a much higher crushing st per square inch than timber piles. Moreover, timber piles do not hav FORM CROSS-SECTIONS. For instance, a slender timber pile 40 ft in leng 12 in in diameter at the butt, is probably not over 6 in in diameter at the In direct compression the load on a point-bearing pile of the above dim is limited to the safe load on the point of the pile, where it is 6 in in dia and a cylindrical concrete pile, 12 in in diameter and under similar con will have a cross-section of 113 sq in at all points, compared with the section of 28 sq in at the point of the timber pile. Moreover, if we c both piles as LONG COLUMNS, it must be borne in mind that a timber pile n be straight and that it may, therefore, be subject to STRESSES and DEFOR due to ECCENTRIC LOADING, which are avoided in a straight, concrete pil

Reinforced-Concrete Piles. In practice concrete piles are general forced, and if a pile is to be considered as a long column the reinforceme be increased at the center, so as to provide for stresses due to handling its acting as a long column. The concrete piles may be formed co above ground, in which case they may be straight or tapered, with squ ular or other cross-sections. The reinforcement may consist of a nu

* American Architect, June 4, 1898, page 78.

† George B. Francis, in American Architect, July 23, 1898.

[...]al rods generally disposed symmetrically around the axis of the pile. The [...]al rods should be connected by horizontal wiring or by spiral reinforcement. [...]fore stated, the reinforcement may be increased at the central section so [...] provide against stresses due to the use of the pile as a LONG COLUMN, in [...] case the additional reinforcement should be placed near the periphery [...]e cross-section.

[...]ypes of Concrete-Pile Reinforcement. There are many TYPES OF REIN[...]CEMENT, one method even employing a woven-wire fabric which is laid out [...] a table and covered with a thin layer of concrete, the entire mat comprising [...]ire fabric and the concrete being then rolled into a solid cylindrical form [...], when set, forms the finished pile. The concrete piles may be FORMED IN [...]E by any one of several different methods.

[...]e Raymond System of Concrete Piling. In this system of concrete [...] a permanent form is provided for each pile. The Raymond system [...]sts of a collapsible steel mandrel or core, tapering from 8 in in diameter [...]e point at the rate of 0.4 in per foot in length, until in a length of 37 ft [...]diameter equals 23.2 in. Upon this expanded mandrel or core is placed [...]rally reinforced sheet-metal shell, the reinforcement of which is grooved [...] the metal on 3-in centers the entire length of the core or pile. This rein[...]ment imparts rigidity and stiffness to the shell, renders it capable of with[...]ing very severe soil-pressure and prevents admixture of foreign substances [...] the green concrete. The combined mandrel and shell is driven into the [...]d to a proper refusal; the mandrel is then collapsed and withdrawn from [...]hell, leaving the shell permanently in the ground; and the interior of the [...]er form is then inspected, and when perfect from tip to top, is filled with [...] concrete. Thus the pile is completed. The extreme taper of the shell, [...]ined with the friction between the shell and the surrounding soil, increases [...]arrying capacity of the pile. The safe load on a Raymond pile varies [...] 15 to 30 tons.

[...]e Simplex Method of Forming Concrete Piles in Place. THE SIMPLEX [...]OD differs from the Raymond method and may be briefly described as [...]s: A steel pipe, generally cylindrical in form, of the required size and [...] and fitted with a detachable cast-iron conical DRIVING-POINT, is driven into [...]round to the required depth; the pipe is then partially filled with concrete. [...]on-like PLUNGER, smaller in diameter than the inside diameter of the [...] is then placed on the concrete and the pipe is partially withdrawn, leaving [...]riving-point and part of the superimposed concrete in the ground. This [...]tion is repeated until the pile is built up to the required height. In cer[...] materials, instead of using a detachable driving-point, the driving-point [...]s of two jaws hinged to the lower end of the pipe, so arranged that while [...] the driving they form a driving-point, when the pipe is withdrawn they [...]nd form an extension of the cylindrical pipe. In other words, the jaws [...]med of steel plates previously bent to the same radius as the radius of [...]pe and so hinged that when they are in their open-position the plates [...]g the jaws constitute an extension of the cylindrical surface of the pipe. [...]vident that plain reinforcing-bars can be placed in position before concrete [...] into the pipe.

[...]on for Concrete Piles Built in Place. Care should be taken in design[...]d placing the reinforcing for all concrete piles BUILT IN PLACE, that the [...]ent placing of the concrete does not throw the reinforcement out of [...] and that all voids between the reinforcement and the shell are com[...]y filled.

The Pedestal Pile is designed to give an ENLARGED CROSS-SECTION a base of the pile. The method is similar to that of the RAYMOND METHOD increase in diameter being obtained as follows: After the pipe has been d the driving-core is withdrawn and the pipe partially filled with concrete. the concrete in the pipe is rammed, forcing the concrete out of the pipe and pressing the material below the pipe, so that the concrete is forced into th A repetition of this operation results in forming a BASE or MUSHROOM belo pipe larger in diameter than the diameter of the pipe. Finally the pipe is drawn, the filling and ramming-operations continuing meanwhile, until th is carried up to the required height.

Composite Piles. Protected piles, for use in localities where the TE affects the life of timber piles under water, are composed of timber piles concrete coatings held in position by steel reinforcements in the shape of exp metal or wire netting. Such piles are to be considered as timber piles than as concrete piles.

Timber Piles with Concrete Caps. In some localities where the perm water-level is considerably below the level of the required excavation, t piles have been driven with a FOLLOWER, the follower consisting of a stee or cylindrical shell. When the head of the pile is driven to a safe dis below low water the PIPE-FOLLOWER is filled with concrete and withd leaving the concrete pier resting on a timber pile. This composite pile appear to possess the advantage of combining the cheapness of a timbe below the water-level with the permanency of a concrete pile above the level. Great care, however, should be used in adopting this method on ac of the difficulty of securing proper connection between the concrete an wooden pile.

The Methods used in Driving Built-up Piles are practically the as are used in driving wooden piles, except that a CUSHION of wood, ro other material is placed on the head of the pile to be driven to cushion the of the hammer. Steam-driven or air-driven RECIPROCATING HAMMERS are erable to the ordinary DROP-HAMMERS. In stiff materials the use of a w JET is advisable and, in fact, in many cases indispensable. In lifting co piles use is made of a special SLING which is attached to a pile at two points point one-quarter of the length of the pile from the end. The sling should a SPREADER so that the stress due to the oblique pull of the CHAIN-SL taken up by the spreader rather than by the pile.

The Casting of Concrete Piles. Concrete piles should be CAST I PIECE by a continuous operation so that there will be no PLANE OF WEA formed between partially set concrete and fresh concrete. They may b either in a vertical position, in forms, or in a horizontal position. Squa tion concrete piles have been cast in a horizontal position and side-forms used, the previously cast concrete pile, protected by paper, forming the b form. In some cases, where it is intended to use a WATER-JET in sinking the latter is cast around an iron pipe which is afterwards used for the jet. In general, however, this is dispensed with and an external deta pipe used for the water-jet.

Incidental Advantages of Concrete Piles. In many cases, where co piles are more expensive than timber piles, the saving in excavation and ings more than offsets the increased cost. For example, if the excavati the cellar of a building does not go down to water-level, the use of timbe will necessitate excavating down to a point below water-level in order th piles may be cut off low enough to keep their heads always wet. Co

s, however, can be driven from the level of the bottom of the cellar-excava- , and this additional excavation and the necessary construction between excavation-level and the level of the cut-off for the timber piles thus avoided. ever, as one concrete pile may have a SUPPORTING POWER equal to the porting power of four wooden piles, the size of the footings will be much ller with concrete piles than with wooden piles.

Comparison of Wooden and Concrete Piles under Piers. The footings a column or pier 24 in sq in section, requiring for its support, say, sixteen oden piles, spaced 2 ft 6 in from center to center, will be, allowing for slight ualities in driving, approximately 10 ft square, the projections being 4 ft nd the size of the base. Such a footing will ordinarily require a steel ge or reinforced-concrete base, or, if made of ordinary concrete, will be of y considerable depth; whereas, if four concrete piles, placed 3 ft from center enter, are used, instead of wooden piles, the area of the base will be a little r 4 ft square and the projection will be only 1 ft. A suitable footing would sist of a reinforced-concrete cap not over 2 ft in thickness. The saving in l of excavation, concrete and steel in the footing is all in favor of the use oncrete piles.

Concrete Piles under Walls. In the case of a continuous wall, where the d per linear foot of wall is not great, a single row of concrete piles is often cient to support the weight of the wall. In such cases, the piles should be placed in straight lines but should be STAGGERED, and a sufficient footing ld be constructed connecting the heads of the piles, so as to afford stability he wall.

The Method Employed in Calculating Reinforcement for Concrete s is the same as that employed in calculating ordinary reinforced-concrete mns, the only difference being that where a pile is not point-bearing, but is ndent on the surrounding material for its support, it need not be considered LONG COLUMN. POINT-BEARING PILES deriving their support from some material on which their lower extremity rests, must be considered as LONG mns, on the assumption that the material surrounding the piles may fail upport them. In the case of FRICTION-PILES, depending for their support the surrounding material, this assumption cannot be made, as any failure e material will involve a settlement of the pile. It should be borne in mind t any structure supported on piles supported by SKIN-FRICTION is dependent its stability upon the continued supporting power of the material surround- the piles. In many cases buildings resting on piles driven into soft ground e settled as the result of the consolidation and settlement of the material unding the piles, notwithstanding the fact that the piles when driven were y able to support the loads for which they were designed.

n-Pipe Piles with Concrete or Reinforced-Concrete Filling have been d in place of wooden or concrete piles, especially in UNDERPINNING-WORK. objection to the use of such piles is that the iron pipe forming the external may rust, in which case the strength of the pile is reduced to the strength e concrete filling and the reinforcement contained therein. The writer ves that they should not be used for permanent work.

ds Allowed on Concrete Piles. The building laws of most cities on concrete piles from 350 to 500 lb per sq in on the concrete plus from to 7 500 lb per sq in on the vertical reinforcement. On this statement ld appear possible to design a short concrete pile 12 in square, on which owed load would be 100 tons, and it is possible that such a pile, tested SHORT COLUMN, would develop in a testing-machine a strength justifying

the use of such construction; but, bearing in mind that the character o support for the base of such a column is underground and cannot be insp and bearing in mind also the uncertainties attending the manufacture o pile, it is evident that it would be improper to load a pile to this extent in pra It would, however, be considered good practice to load concrete piles up tc third of a test-load applied to not less than 3% of the piles used. In ord practice, reinforced-concrete piles are loaded up to 500 lb per sq in of cros tion.

29. Foundation Piers and Foundation Walls

Foundation Piers and Walls as distinguished from ordinary CELLAR and WALLS, extend from the level of the underside of the cellar-floor to ro other solid foundation-bed. (See page 129, Subdivision 1, and also Ch III, pages 228–9.) In general, such piers and walls are composed of co and are of such dimensions that the safe unit loads on the concrete fo them are not exceeded. If the foundation-bed is rock, compact hard-pa gravel, there need be little or no enlargement of the base of the pier or wa the safe unit loads on such natural foundation-beds are generally equal t safe unit loads on the concrete forming the body of the pier or wall. The o of such piers and walls is therefore an entirely simple matter governed b principles already outlined, and by certain considerations mentioned here

The Methods used in the Construction of Foundation Piers Walls are, however, necessarily varied to suit different materials and to different conditions encountered, and the design of a pier necessarily differ different methods of construction. For example, if the construction is executed by means of the ordinary SHEET-PILING METHOD, piers and wal have in general rectangular outlines. But if the CHICAGO METHOD or the MATIC CAISSON is employed, it will generally be cheaper to use piers ha circular cross-section and the support for walls may be a succession of cyl rather than continuous walls. The detailing of the concrete structure c tuting the piers or walls is simple after a determination is made of the me by which the construction is to be put in place. This subject is discussed following chapter-subdivision, Methods of Excavating for Foundations.

30. Methods of Excavating for Foundations

Simple and Complex Excavations. Excavations in earth for footi walls and piers may vary from simple trenches and pits of the require and depths to accommodate the footings, up to deep subaqueous excav requiring all the resources of engineering skill.

The Sides of Excavations. If the earth is firm and the depth not ex the sides of the excavation may be self-supporting, in which case the exca may be made the neat size of the footing and the sides of the excavatio take the place of forms for the concrete deposited to form the footing. the excavation is deep, and especially where the earth is not firm, the s the excavation must be sloped or, if made vertical, must be supported by b or by some form of sheet-piling. Where the excavation is over 8 ft in d will generally be cheaper to support the sides of the excavation than t them. Where the excavation adjoins a property-line it will generally b visable to slope the excavation on account of damage to the adjoining pr and in such cases it will be necessary to use sheeting, even if sloping th would be cheaper.

bracing in many cases will serve to support the sides of the excavation without the necessity of close SHEETING. The BRACING may consist simply of short pieces of PLANK placed against opposite sides of the excavation and held in position by horizontal timber STRUTS secured by WEDGES; or, especially in narrow trenches, some form of EXTENSIBLE SEWER-BRACE may be used. Fig. 34 represents a usual form of EXTENSIBLE BRACE. Generally, however, the sides of an excavation will not stand with a vertical face, even if braced in this manner, for any length of time, and if the material is sand or soft clay, such bracing is entirely inadequate. In such cases, and in fact generally, some form of CONTINUOUS SHEET-PILING must be employed.

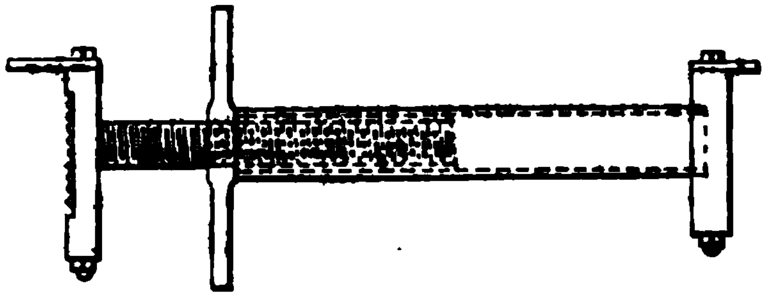

Fig. 34. Extensible Brace for Narrow Excavations

Ordinary Wooden Sheet-Piling consists of a continuous line of vertical planks held against the sides of the excavation by horizontal timbers known as WALES, WALING OR BREAST-TIMBERS, these wales, or breast-timbers being in turn supported either by CROSS-BRACES extending across the excavation to an opposite wall or side of the excavation, or by inclined struts known as SHORES or RAKERS, extending to the bottom of the excavation where HEELS or inclined platforms are sunk in the undisturbed material to afford points of support.

Earth-Pressure on Sheet-Piling. The load on the sheeting due to the EARTH-PRESSURE may be calculated on the assumptions made for the design of RETAINING-WALLS, but the thickness of the sheeting planks, the sizes and spacing of the breast-pieces and braces, if figured on this basis, will in general exceed the sizes constantly used with success and safety in such work. The probable reason for this is that an earth bank, when steadied and in part supported by the sheeting, does not, for a considerable time, lose the COHESION between its particles natural to most earth banks in their original and undisturbed state. Or, in other words, under these conditions no real ANGLE OF FRICTION is developed in the earth-mass. Local experience and practice should be consulted and will usually serve as a guide. Earth banks apparently similar will, however, act very differently and no general rule can be given. It should be borne in mind that the earth composing a bank should be, as far as possible, protected from drying, from the action of water and from alternating freezing and thawing; and that permanent work should be completed as rapidly as possible so as to avoid the deteriorating effects of time and exposure on the structure of the bank.

The Thickness of the Sheeting Planks required may be calculated on the assumption that the earth bank is composed of loose material having a definite ANGLE OF SLOPE and COEFFICIENT OF FRICTION; but practically, under favorable conditions, 2-in planks may be used for a depth of drive of 16 ft, 3-in planks up to 24 ft and 4-in planks up to 32 ft; and timbers, 8 by 12 in, have been driven in suitable material to a depth of over 40 ft.

Depths and Numbers of Drives. Ordinarily the depth to which a plank can be driven is limited by its ability to resist the shock due to driving, and in unsuitable material a plank may become shattered before it is driven to the above-quoted depths. If the required depth cannot be reached by the first planks driven, a second, and sometimes a third and fourth set of planks are employed. The BREAST-PIECES supporting the first line of planks must remain in place,

the planks in the second set or DRIVE have to be placed inside of the b
pieces, thus reducing the size of the excavation by the amount of the nece
offset. Where more than one drive is required the first drive should be st
at a sufficient distance outside to allow the planks forming the second o
second and third drives to be placed outside of the required area for the
tom of the excavation.

Cutting and Fitting Sheeting Planks. The sheeting planks ma
SQUARE-EDGED where there is no water or fine loose sand, but where
or running sand is to be excluded the planks should be TONGUED
GROOVED, or SPLINED. The use of tongued and grooved planks ha
additional advantage that the planks are more readily kept in line.

Fig. 35. Small Power-hammer for Driving Sheeting Planks

Fig. 36. Large-size Power-hammer and Sheeting Planks

usual to cut the bottom edge of each plank on a slight angle, so that in dr
it is WEDGED against the preceding plank. The top of each plank may be f
to receive an iron DRIVING-CAP; or, if this is not used, the upper corners o
plank should be cut off so that the effect of the blows will be concentr
along its vertical axis, and the tendency of the plank to SPLIT, due to a
on one corner, thus diminished.

The Means Employed for Driving the Sheeting vary with the d
and the size of the sheeting. For small jobs and for moderate depth
drive, the primitive method of DRIVING BY HAND with ringed wooden m
still prevails. For work involving a considerable amount of driving, and i
cases for long drives, POWER-HAMMERS driven either by steam or compresse
are preferably employed. A small-sized power-hammer (Fig. 35) resemb
STEAM-DRILL and may be handled by two or three men without any special lif

...tion. The larger sizes of power-hammers (Figs. 36 and 37) are practically ..., power, pile-driving hammers arranged with a special DRIVING-HEAD to ... the sheeting employed. Such hammers are handled by DERRICKS or are ...ied in a frame similar to a pile-driver frame. Ordinary DROP-HAMMERS ...sometimes used, but are not as advantageous as the RECIPROCATING POWER-...MERS, as the blow struck by the drop-hammer ...ures the plank, while the frequent light blows ...the power-hammer tend to keep the planks and ...adjacent material in motion and accomplish the ...quired work with less damage to the sheet-piling. ...weights and dimensions of several types of pile-...ving hammers are given in Table XI, page 204.

...anner of Driving Sheeting Piles. In prac-...ice, a shallow excavation is first made to the ...per line for the outside of the sheeting planks. ...he top BREAST-TIMBER is temporarily secured in ...ace and the lower end of the planks placed be-...ween this timber and the bank. If the planks ...re long, temporary TOP GUIDES or STAY-BRACES are ...ranged so as to keep the planks vertical until ...ey have been driven well into the ground and ...ured by the permanent BREAST-PIECES. The ...anks are then driven as the excavation pro-...resses, each plank being driven a few inches in ...rn. As the driving goes on the material under ...e lower edge of the planks is loosened with a ...ovel or with a crowbar, the operation being so ...ducted that the planks are held true to line. ...he horizontal breast timbers and their braces are ...aced in position as the excavation progresses. ...inclined braces are to be used the excavation in ...e center is taken out first, leaving a sloping bank ...ainst the sides of the excavation. This permits ...the placing of the inclined braces and of the ...ds for their points of support before there is any ...nger to the bank. After the first breast piece ...d its inclined brace are set in place, the second ...d subsequent breast-pieces and braces are put in ...the excavation proceeds.

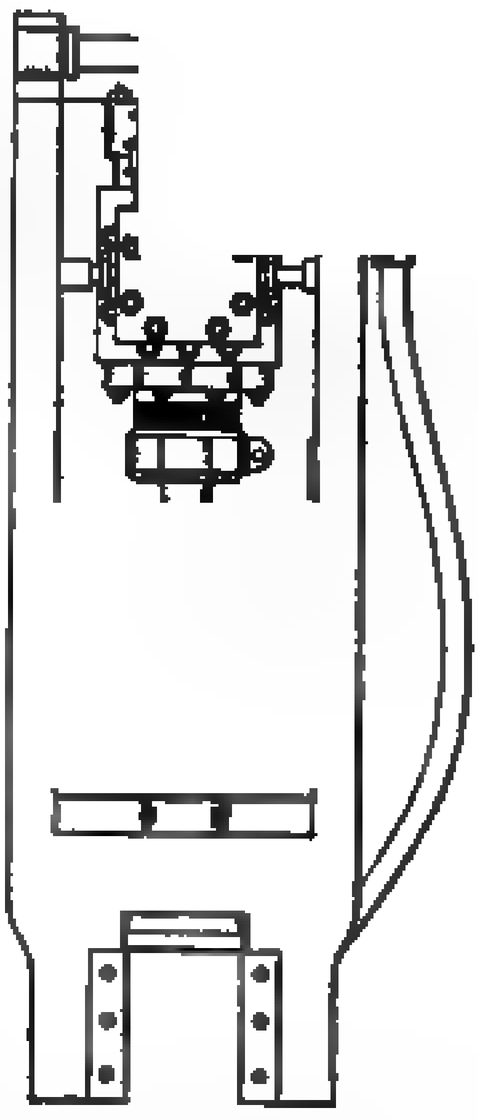

Fig. 37. Large-size Power-hammer for Driving Sheeting Planks

...eet-Piling for Excavations Below Water-...el. These excavations may be made by ...SHEET-PILING METHOD if there is not too much water and if water can ...ained out of the material without inducing a flow of sand or clay below ...bottom of the sheet-piling. In some cases, where unfavorable conditions ...t, but where there is an underlying stratum of impervious material, it is ...ible to drive the sheeting in advance of the excavation, so that the bottom ...e sheeting makes a tight joint with the impervious stratum, cutting off the ...of water and material. Where a considerable amount of water finds its ...into the excavation, the water must be led to a SUMP or depression from ...it is ejected by means of a PUMP or a STEAM-SYPHON. Where the founda-...d is below water-level and the material is sand, clay, or other material ...would be softened by the action of the water, it should be protected by ...g the sump at a considerable distance from the area to be used for the sup-

of the footing. This may be accomplished by making the area to be sheeted excavated large enough to accommodate the sump outside of the supporting area, or by sinking a separate excavation to be used exclusively as a sump; the same result may in some cases be accomplished by the use of DRIVE-WELLS, driven to a point below the level of the footing in which continued pumping may reduce the level of the water to a point below the footing. Care should be taken, when the level for the footing is reached, to prevent the foundation-bed from being disturbed and softened by unnecessary tramping of workmen over the surface of the excavation.

The foundation-bed should be left as nearly as possible in its original or natural condition.

Steel Sheeting has been largely employed recently in place of wooden sheeting. It has the advantage that it can be driven in advance of the excavation, thereby reducing the likelihood of any flow of material under the sheeting. It also has the advantages of affording greater strength for a given thickness of sheeting, of being driven to a greater depth, and in many cases of being withdrawn and used over again. As generally manufactured, it has the further advantage of being INTERLOCKING, so that there is less danger of its getting out of line and leaving openings between adjacent pieces.

All of these advantages have been considered by engineers in using steel instead of wooden sheeting.

The Use of Steel Sheeting. The fundamental idea of steel sheeting is not new, as CAST-IRON SHEET-PILING was used in England as far back as 1822 and various combinations of steel plates have been used in coffer-dams. The general use of steel sheeting started in this country in 1899 when Luther P. Friestedt made experimental INTERLOCKING CHANNEL-BAR SECTIONS. Since that time it has come into general use, and with its aid many excavations have been made with STEEL SHEET-PILING which would have been impracticable with timber sheeting.

Earth-Pressure on Steel Sheeting. In using STEEL SHEETING, it should be borne in mind that the EARTH-PRESSURE coming on the steel sheeting is the same as the earth-pressure coming on timber sheeting, and the breast-pieces and braces should be as strong as in the case of timber sheeting. Certain forms of sections of steel sheeting offer considerable resistance to bending due to the lateral earth-pressure. With such forms the horizontal breast-pieces may be spaced farther apart than with ordinary timber sheeting or steel sheeting not having this property; but the strength of the breast-pieces and of their braces must be sufficient to take up the entire load coming on the sheeting, irrespective of the spacing between such breast-pieces, for in case there is a failure in these the entire sheeting will fail.

Different Forms of Steel Sheeting. Various TYPES OF STEEL SHEETING are on the market. In making a selection between different forms of sheeting, the character of the material to be encountered should be borne in mind, as the simpler, more compact sections will penetrate hard or gravelly soils with less danger of deformation than the more complicated sections made up of thin plates and shapes. The various companies manufacturing different forms of sheet-piling publish catalogues containing data as to the weight and also giving properties of the different sections. These catalogues may be obtained from the manufacturers, but for convenience illustrations of some of the principal sections, with their dimensions and weights and other details, are given in the following pages.

There are other types of steel sheeting than those shown in Figs. 38 to 44.

e Poling-Board or Chicago Method is a special method of excavation neral use in Chicago and in occasional use elsewhere for excavations which o a great depth in clay or in other suitable material. It has the advan- over the ordinary sheet-piling method that the lining of the excavation is driven. The method is not generally used for trenches or for square ex- tions as a circular excavation is more readily handled. The success of the hod depends entirely upon the character of the material to be encountered, he excavation is first made and the sides of the excavation afterwards orted. The method in detail for a circular excavation for a pier-foun- n may be described as follows:

) A circular excavation slightly in excess of the size required for the pier ried down to a depth of 5 ft, great care being taken to have the sides of excavation vertical and true to the circle.

) Vertical planks called LAGGING-PIECES, 5 ft in length and slightly beveled heir edges so that each piece may be considered as a stave with radial joints sponding to the size of the required circle, are set in place against the walls e excavation. These planks are held in place by two or more steel rings, ally made in quadrants, so that they may be conveniently handled and d together. The planks are wedged firmly against the walls of the excava- by means of wooden wedges driven between the planks and the iron rings.

) As soon as the first set of lagging is complete, the excavation is carried n for another section, 5 ft in depth, and another section of lagging is put in e and secured in the same manner.

pth and Character of Excavations in the Poling-Board Method. In the er described above the excavation may be carried down for an indefinite nce, a depth of 100 ft having frequently been attained. In many cases bottom of the excavation is BELLED OUT to a larger diameter than the ex- ion for the main shaft of the pier with the object of reducing the load of ndation-bed to a unit load less than the safe unit load on the main shaft of ier. This method is not adapted for running sand nor for clay that is not enough to stand with vertical sides during the necessary interval between g the excavation and placing the lagging. In some cases where a stratum uicksand has been encountered, the excavation has been carried past it

by the use of a cylindrical shell of steel, forced by jacks through it to an lying impervious layer of clay; but in general this method is dependent success upon a continuous body of impervious material.

The Open-Caisson Method or Well-Curb Method is used for pier carried to a considerable depth, and has advantages over the sheet-piling in certain materials. It is a development of the old method used in masonry wells and, in its modern form, consists of a structure which eve forms part of the pier itself and which is arranged with an open chambe base in which men may excavate the material under the structure and to settle as the excavation proceeds. It is evident that a central ope shaft must be left in the structure to permit of the passage of men and m

Details of the Open-Caisson Method. In detail, the method may be de as follows: First a CURB or CUTTING-EDGE of timber or steel, following t line of the pier, is constructed on the surface of the ground. The out of this curb is generally vertical and is protected with a steel plate wh tends below the main section of the curb, so as to form a cutting-edge o downward projection serving to penetrate the soil slightly in advance excavation. On this curb a wall of timber, concrete, or masonry is const inside of which the so-called WORKING-CHAMBER affords room for the w to be employed in excavating. Above the working-chamber the walls ma tinue to a height corresponding to the required height of the pier, leavi central space to be filled in after the required depth is reached; or a ro be built over the working-chamber and the entire cross-section of the pi with concrete or masonry excepting only a small central opening large en accommodate a HOISTING-TUB or BUCKET and to permit of the ingress and of the men employed in sinking the construction. In practice, the exca is started before the pier-structure is carried up to its final height, after the excavation and the building up of the pier progresses simultaneous constantly increasing weight of the structure aiding the sinking of th When the excavation has reached rock or a firm substratum, further e tion is stopped and the working-chamber and the central opening are full of concrete, leaving finally a complete pier-structure extending fr rock to the proper level to receive the steel grillage or other constructio ing on the pier.

Advantages of the Open-Caisson Method. This method of constructi the advantages that the workmen at all times are protected, that obstru such as boulders or logs, may be removed from under the cutting-edg that when rock is encountered, ample opportunity is afforded for the preparation of the rock-surface to receive the final concrete filling. If a mo amount of water is encountered, not accompanied by a flow of material, generally be taken care of by means of pumps.

Dredged Wells are similar to the open caissons described in the p paragraphs and are used where large quantities of water are encountered construction of the piers is similar to that of the piers used in the open- method; but the central shaft and working-chamber are designed to of the use of a CLAM-SHELL DREDGE or other form of dredge, and the w allowed to rise to its natural level in the working-chamber and shaft. method can be used to advantage when a considerable amount of water-b sand or other material is found overlying level rock or other firm found bed. When the dredging and the sinking of the pier-structure have been down to the hard underlying strata it is sometimes possible to pump o water. If this is not practicable the bottom may be prepared by divers reception of the concrete filling, and the concrete may be deposited through

...ing taken to use some special arrangement to protect the concrete from ...injured by loss of its cement-content, in the process of deposition.

...he **Well-Digger's Method** is also occasionally used in making PIT-EXCAVA... under walls or in cramped locations. By this method the sides of the ...ation are supported by planks placed horizontally. The method of plac... the planks is as follows: A shallow excavation, the depth of a plank, ...de by ordinary methods, and a SET, consisting of four planks fitting the ... sides of the excavation, is secured in place. Before proceeding with the ...al excavation of the pit a trench is dug directly alongside and underneath of the side planks of the FIRST SET. As soon as this trench is deep enough to ...modate the planks for the SECOND SET, the side of the trench under the ... already in place is cut to a vertical face, the plank placed in position and ...loose earth temporarily back-filled against it. As soon as the four planks ...ing the SECOND SET have been put in place by this method, the two side ...ks are wedged against the bank, the end-planks being used as struts. The ...planks are wedged into position and nailed or cleated to the side planks ...ing a PRESSURE-RESISTING FRAME supporting the side of the excavation. ...tinuation of this method enables the excavation to be carried on indef...ly, provided there is no flow of water or run of material causing an inflow ...terial into the excavation.

...he **Pneumatic-Caisson Method.** Where piers or foundation walls have ...e carried to a considerable depth through water-bearing materials, and espe...ly where large bodies of quicksand are encountered, the PNEUMATIC-CAISSON ...od must be resorted to. This method is based upon the PRINCIPLE OF A ...-BELL and may be briefly described as follows: The construction of the ...is similar to the piers previously described as used in the open-caisson and ...ed-well construction, except that the working-chamber and shaft are made ...ight and connected with a device called an AIR-LOCK, so that compressed air ... be introduced into the working-chamber. The object of the compressed ...is to prevent water entering into the working-chamber. This is accomplished ...cordance with the well-known PRINCIPLE OF THE DIVING-BELL by having ...compressed air constantly kept at a pressure which will counterbalance the ...-pressure at the level of the cutting-edge of the working-chamber. The ...ure of the air evidently must vary with the depth of the cutting-edge below ...-level. A column of water 1 in square in cross-section weighs .43⅓ lb per ...al ft, and it will therefore be counterbalanced by an air-pressure of .43⅓ ... sq in over the normal air-pressure. If the column of water is 30 ft in ...t, it will weigh thirty times .43⅓ lb, or will be counterbalanced by an air-...re of 13 lb per sq in above the atmospheric pressure.

...e **Maximum Air-Pressure in the Pneumatic Caisson** in which men can work ...ort periods is about 43 lb per sq in above atmospheric pressure, correspond...o a depth below water-level of about 100 ft. At this depth the work is ...d on in shifts of from two to three hours duration, and great care must ...ercised in coming out of the AIR-PRESSURE. The physiological effects of ...ssed air are often serious; pains in the joints, damage to the ear-drums ...g in deafness, and the so-called CAISSON-DISEASE render work at high ...e extremely hazardous.

...**Air-Lock Used in Connection with the Pneumatic Caisson** is a device for ...pose of retaining the air in the caisson and at the same time permitting ...age of men and material in and out. It consists essentially of a metallic ...ir CHAMBER or SHELL connected to the working-chamber either directly ...n air-tight lining or extension of the central shaft-opening. This air-...r has two doors, one at the bottom, opening downward into the shaft

and the other in the upper head of the air-lock chamber, also opening ward and affording a direct connection to the open air. In the operation air-lock one of these two doors must at all times be closed so as to preve free escape of air through the air-lock. If the bottom door is closed, it held firmly to its seat by the uplift of the compressed air in the shaft, wh at all times in direct communication with the working-chamber. If, under conditions, the upper door is open, the interior of the air-lock will be in communication with the open air and the air contained in the lock will evi be at atmospheric pressure. Workmen and materials may then enter t lock. In order to pass into the shaft and working-chamber, it is nece first, to close the upper door, and secondly, to shift the so-called EQUA VALVE and admit compressed air into the space between the two doors the air-pressure is brought up to the air-pressure in the working-chamb shaft. Pressure on the upper side of the lower door will then equal the p on the lower side and the lower door may be opened, the upper door being held against its seat by the compressed air in the air-lock. As soon as the door opens, the men and material may be passed into the shaft and wo chamber. In coming out the operations are reversed; men and material the air-lock through the open lower door, the lower door is closed and held against its seat, and the equalizing valve is shifted, affording a connecti tween the interior of the air-lock and the external air. The compress escapes through the equalizing valve, reducing the pressure in the air-l atmospheric pressure, and the upper door has atmospheric pressure o sides of it. It may then be opened, giving free connection with the outs

The Design of Pneumatic Caissons. The first consideration is, of cou have the final structure a permanent and sufficient pier to carry the loa imposed upon it. To this end the cross-section of the pier at all points fr to bottom should be capable of carrying safely the maximum load. cross-section of the pier is generally, in the finished pier, composed of sol crete, the cross-section will be determined by the allowable load on the co For piers the cross-section will generally be square or circular; for wa caisson will generally be not less than 6 ft in width, as it is difficult caissons having a width less than 6 ft. If the caisson is to be carried rock, the bearing on the rock need be no larger than the cross-section concrete pier; but if the excavation does not go to rock, it is frequently able to BELL OUT the base of the pier so as to reduce the loading on the tion bed to a unit load less than that allowable on concrete. The opera BELLING OUT is difficult in some materials; in a compact material it can erally accomplished without serious difficulty.

Piers Sunk by the Pneumatic-Caisson Method may be constructed of combinations of materials. The side walls and roof of the working-c were formerly frequently constructed of timber. In many cases they formed of steel; but in recent designs the working-chamber is generally of reinforced concrete, the only structural steel used being an angle or and angle composing the cutting-edge. The outside of the caisson is pr made vertical. The superimposed pier is generally of the same size as th ing-chamber, at least it is generally so in piers sunk for buildings.

A Typical Design for a Caisson Built of Reinforced Concrete is given in in which *AB* is the angle-iron and plate forming the so-called CUTTIN and *C* is the WORKING-CHAMBER formed by the side walls *DE* and *DE* the roof *EE*. The concrete side walls are reinforced with steel rods atta the cutting-edge, and extending upward into the body of the pier, and and body of the pier are reinforced to take care of stresses due to c

[illegible]sinking. In building up the working-chamber, the INTERIOR FORMS are [illegible] so as to support the concrete which makes the roof. These are sub-[illegible] removed. The exterior forms may constitute a permanent part of the [illegible], in which case they are called a COFFER-DAM, or they may be removed [illegible] the concrete has sufficiently set. At the center of the pier an open-[illegible] left to serve as the [illegible] opening connecting [illegible]ing-chamber with the [illegible]. The sides of this [illegible] of the upper part [illegible], are lined with an [illegible] STEEL SHELL. To [illegible] end of the steel [illegible] air-lock is connected. [illegible] of the pier does [illegible] 40 ft the construc-[illegible] may be completed [illegible] the excavation is com-[illegible]. Generally, however, [illegible]struction of the pier is [illegible] as soon as the work-[illegible]ber and from 5 to 10 [illegible] the superimposed pier [illegible] constructed; then [illegible] excavation is done, [illegible] the use of compressed [illegible] carry the cutting-edge [illegible] water-level. This is [illegible]ITCHING THE CAISSON [illegible] so that the caisson [illegible] some slight lateral [illegible] from the soil before [illegible]struction is carried up [illegible] to make it top-[illegible]. When the entire pier [illegible] first section is finished, [illegible] is resumed and the [illegible]structure is sunk as the [illegible] progresses, care be-[illegible] to remove any [illegible] from beneath the [illegible]edge. During the progress of sinking compressed air is conducted to [illegible]ing-chamber through the SUPPLY-PIPE *G*, the excavated material being [illegible] through the SHAFT *F*. The shaft *F* is fitted with a LADDER for the use [illegible]workmen.

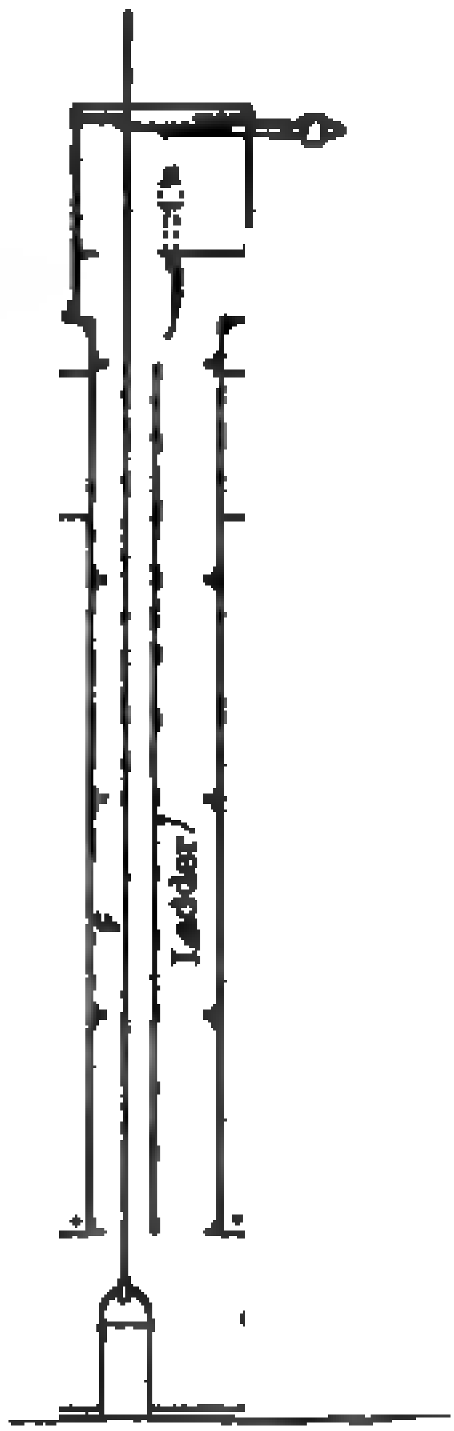

Fig. 45. Typical Form of Reinforced-concrete Caisson

[illegible] of Caisson-Sinking and Filling. In sinking the caisson and super-[illegible] pier, care must be taken to maintain it in a vertical position. This [illegible] be accomplished in large caissons by means of the excavation itself. [illegible] one side of the caisson is high the excavation on that side will be carried [illegible] in advance of the excavation on the low side, and the material under [illegible]-edge of the high side will be removed while a bank of material is [illegible] the cutting-edge of the low side. These methods, however, are of [illegible] when the caisson is narrow. In such cases that part of the caisson [illegible] above ground is held in position by GUIDES or other devices; but it

frequently happens that the caisson in its final condition is considerabl its correct location and considerably out of plumb. In general, there size of the caisson should be made larger than the minimum size nec order to allow for errors in its final location. When the caisson has rea required depth the foundation-bed is prepared for the reception of the filling and the working-chamber filled with it, care being taken that it co fills all voids and is in perfect contact with the roof. Finally, the air the steel lining of the shaft are removed and the shaft-opening filled crete to the proper level to receive the GRILLAGE or other construction the base of the column which is to rest on the caisson.

The Height of Caisson-Piers. The height of a pier cannot be fixed until it is known to what depth the caisson must sink in order the foundation-bed. If the rock is found at a greater depth than ant additional height is added to the top of the pier after the caisson is in position; but if, on the other hand, the rock is found unexpectedly l top of the pier will have to be cut off. If the finished elevation of the be below the level of the general excavation, it is usual to extend the surface of the pier to the required height by means of a temporary structure called a COFFER-DAM, the height of which corresponds to the the finished surface below the level of the general excavation. Insid COFFER-DAM some STEEL GRILLAGES may conveniently be set.

The Freezing Process for Excavations. This method has s been employed in making excavations. In this country its use has bee to one or two mining-shafts, but in Germany it has been resorted to in excavations for building-foundations. The method consists in driv pipes into the ground. These pipes are closed at the bottom and at are connected to smaller pipes through which brine, at an extremely l perature, is made to circulate. The refrigerating effect results in free water contained in the soil, converting quicksand to a frozen mass re soft sandstone. When the freezing has progressed sufficiently to form wall or coffer-dam around the excavation, the material inside the fro may be excavated. This method has the advantage, theoretically, applicable to excavations of any depth. There are many precautions n and for the present, at any rate, it should only be considered as a possil

31. Protection of Adjoining Structures

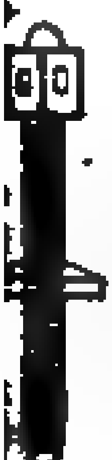
General Considerations. The COMMON LAW provides that any pers ing an excavation is responsible for resulting damage to adjoining STATUTE LAWS as embodied in the building codes of different cities ma or limit this responsibility, but in general, excavations should be mad a manner as to cause the least possible damage to surrounding property. there are no adjoining structures it is generally sufficient to slope the sid excavation so as to prevent the sliding of material into the excavatio least, to sheet-pile and brace the sides of the excavation; but where the tion is to be made alongside of an existing structure, and carried b footings of such structure, it is necessary to take special measures for it tion. Such work is described as SHORING, UNDERPINNING and PROTEC JOINING STRUCTURES, and may involve the carrying of the weight of p of the buildings on temporary supports, the removal of the old foot the construction of new footings at lower elevations.

Shoring. When the excavation for the new building does not below the adjoining footings and when the material is fairly solid, it m to transfer a portion of the load of the wall to temporary footings. Thi

plished by means of heavy inclined posts called SHORES, arranged to act
...ing COLUMNS or STRUTS. Each SHORE consists of a post, the lower
... which rests on a PLATFORM, generally consisting of planks and timbers
... so as to form a temporary spread footing. This platform should be
... at a depth which will insure that subsequent operations will not under-
...it. The upper end of the post fits into a hole or niche cut into the wall
... supported. The post itself may be a timber with a square cross-section,
... 12 by 12 in. and of the required length. Provision is made, between the
... and the lower end of the post, for WEDGES or JACKS, so that when
...ed their lifting effect transfers part of the weight of the wall from its
... to the temporary foundation or platform. During this operation all
... of the temporary structure are in compression and brought into bearing,
... material under the platform is compressed and solidified as much as
...le.

...s of Shores. If the SHORE is to act preferably for LIFTING only, it is
... nearly vertical as possible and is known as a LIFTING SHORE. If it is
... preferably to combine a horizontal PUSHING action with the lifting
..., it is placed at a considerable angle from the vertical and is then known
...SHING SHORE or STEADYING SHORE. In arranging such shores care
... be taken to have the niche cut close to a floor-level of the building to be
..., as otherwise the horizontal component of the thrust of the shores might
... the wall.

...s and Sizes of Shores. Where a wall is light, a number of smaller ... should be used in preference to a few large ones. Where a wall is high, ...r more shores of varying ... may be used, and these ...conveniently be placed in the ... vertical plane and rest on the same platform.



... Standard ... of Steel ...-jack

Wedges and Screw-Jacks. In transferring the load of a wall from its own footing to the temporary platform, use is made of wooden or steel WEDGES, SCREW-JACKS, or HYDRAULIC

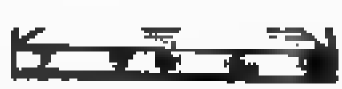


Fig. 47. Standard Type of Steel Screw-jack

...s, wedges and jacks may be used in combination. Wooden wedges ... be made of hard wood and are generally arranged in pairs, both ... being driven at the same time. The lifting effect of such wooden ... is powerful, but where a considerable settlement of the temporary ...m is anticipated, it is more convenient to use screw-jacks, as they ... up a considerable settlement.

...ls and Types of Screw-Jacks. The SCREW-JACKS usually manu... for this purpose are made of cast iron and have rough threads, with ... a pitch to have much lifting effect. Screw-jacks of a better kind are ...eel and have a machine-thread of small pitch. Such jacks can be ...pable of lifting weights up to 100 tons. Figs. 46 and 47 represent

standard forms of screw-jacks. When a single screw-jack is used in
tion with a post or shore, a hole to receive the threaded portion of
is bored in the end of the timber used for the shore, the end being sq
receive the nut. Such an arrangement is called a PUMP and is illust
Fig. 48. When a lifting effect greater than that exerted by a single ja
quired, the jacks are arranged in pairs in connection with a short timber c

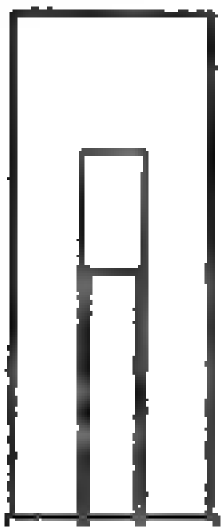

Fig. 48. Pump, or Screw-jack let into End of Shore

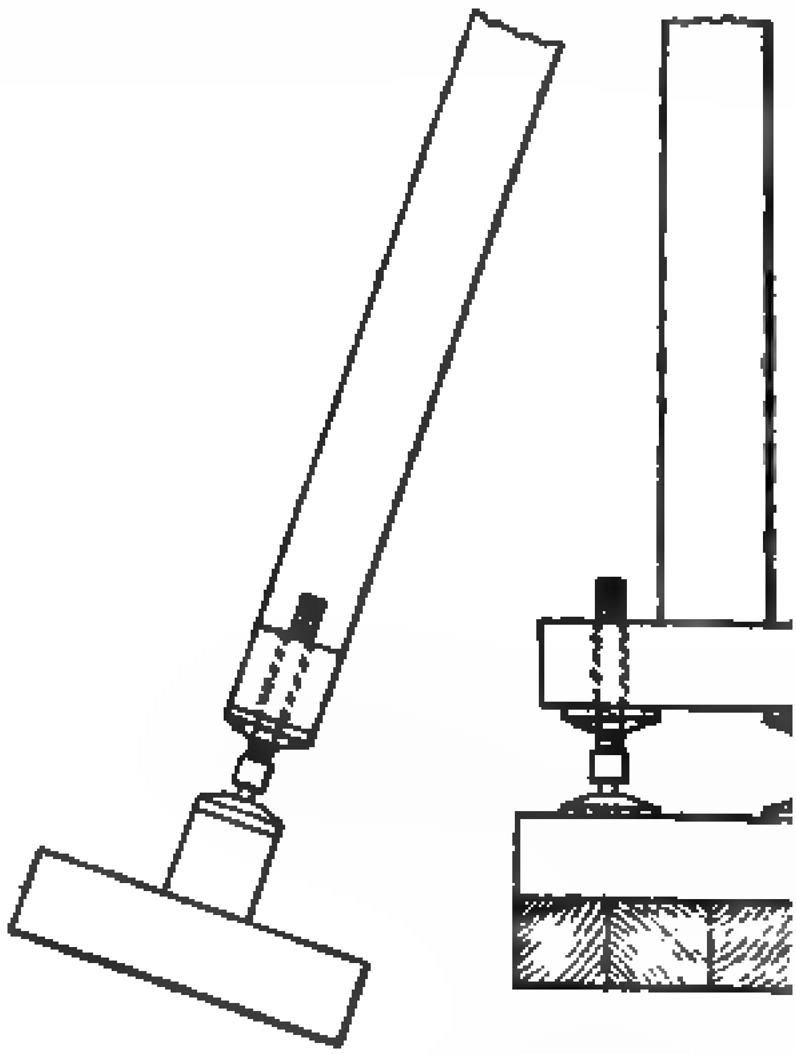

Fig. 49. Shore, Screw-jacks and Timber head

HEAD. Such an arrangement is illustrated in Fig. 49. It has the ac
that after operating the jacks, blocking and wedges can be placed betv
platform-timbers and the cross-head so that the post resting on the cr
has a direct and solid bearing on the platform. By this method the loa
wall can be thrown on the platform by the jacks and after the blocking an
ing is in position the jacks can be removed.

Hydraulic Jacks. Where excessively heavy loads are to be lifted, HY
JACKS may be used in place of screw-jacks but an objection to them is th
are liable to SLACK BACK under the load. While the load, therefore
not be permanently supported on hydraulic jacks, they may be used to
load temporarily while the blocking and wedging are being placed betw
cross-head and the temporary footing. In this way an indefinite nu
shores may be set and taken care of with a single pair of hydraulic jacks

Example of Shoring. Fig. 50 shows the method used in SHORING t
mental front wall of a heavy building, advantage having been taken of
merous deep margin-drafts shown in the section. In order to avoid the
of cutting niches for the tops of the shores, nine hardwood blocks, a,
were fitted to the margin-draft grooves in the masonry. Nine similar
b, b, etc., were gained into and bolted to the vertical timber, V V, spa

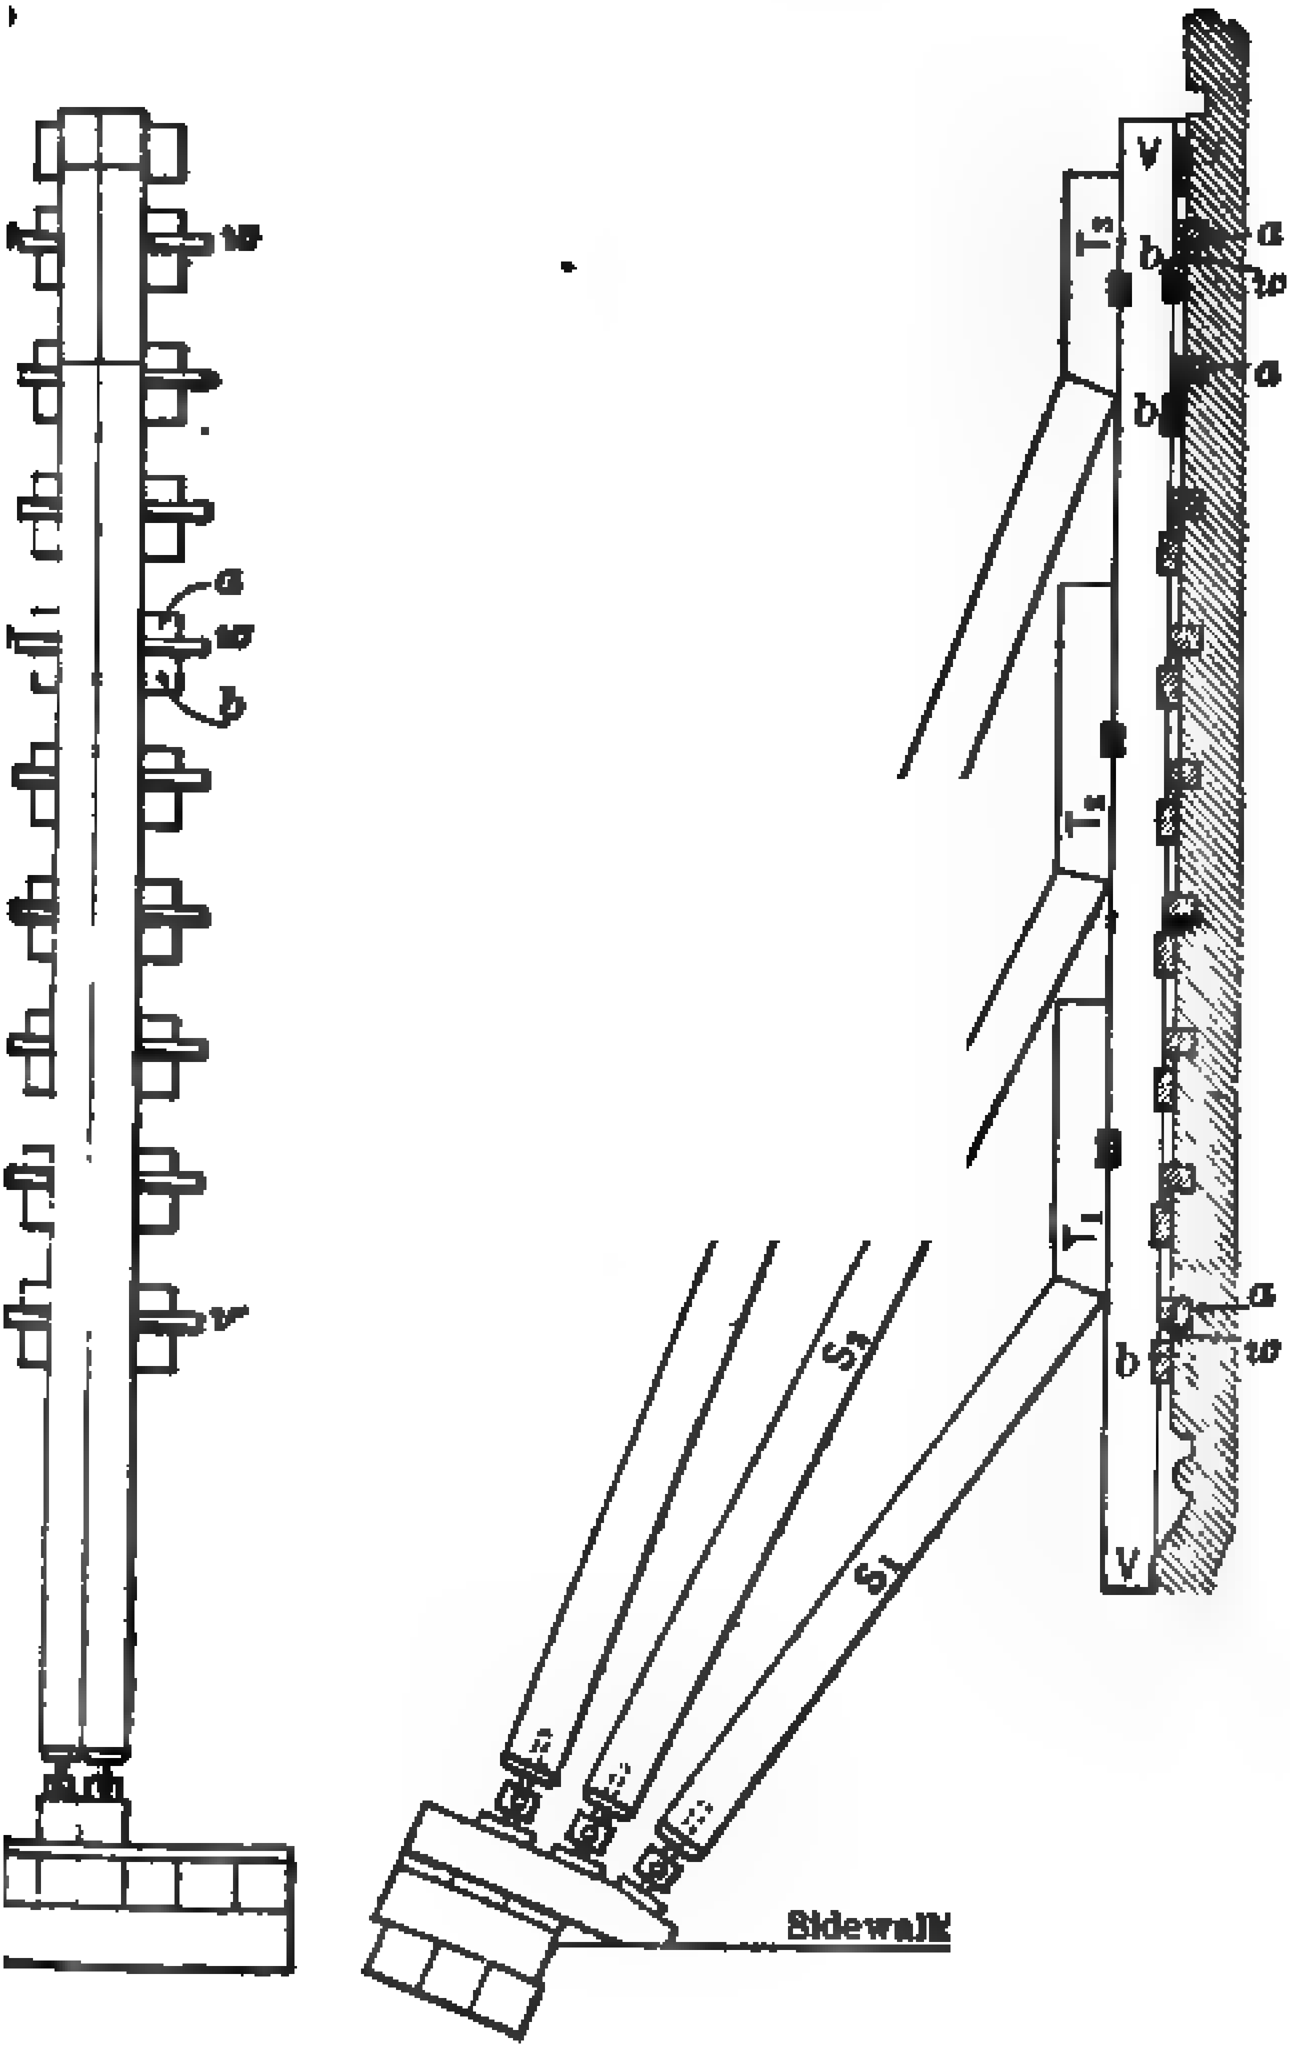

Fig. 50. Shoring an Ornamented Wall

[illegible] the *a* blocks and the *b* blocks for adjusting wedges *w*, *w*, etc. Three [illegible], T_1, T_2 and T_3 were keyed and bolted to *VV* and transmitted to it [illegible] of the three shores, S_1, S_2 and S_3. Each shore had a 60-ton screw-jack [illegible]. Each shore is shown fitted with a pump or detached extension-[illegible] for the screw-jack.

Needling. NEEDLES or GIRDERS are employed when part or all of th of the wall has to be carried, as when the old footing is to be removed wall UNDERPINNED or carried down to a new footing at a greater depth.

Example of Needling and Underpinning. Fig. 51 represents a typica UNDERPINNING, the several operations being as follows:

(1) **The General Excavation** is carried down to within a few inche bottom of the footing *BB* under the wall *W*.

(2) **The Pit** *DDDD*, properly braced and protected by sheet piling, to approximately the level of the proposed excavation, this PIT bein at a safe distance from the existing wall. In good material it may be

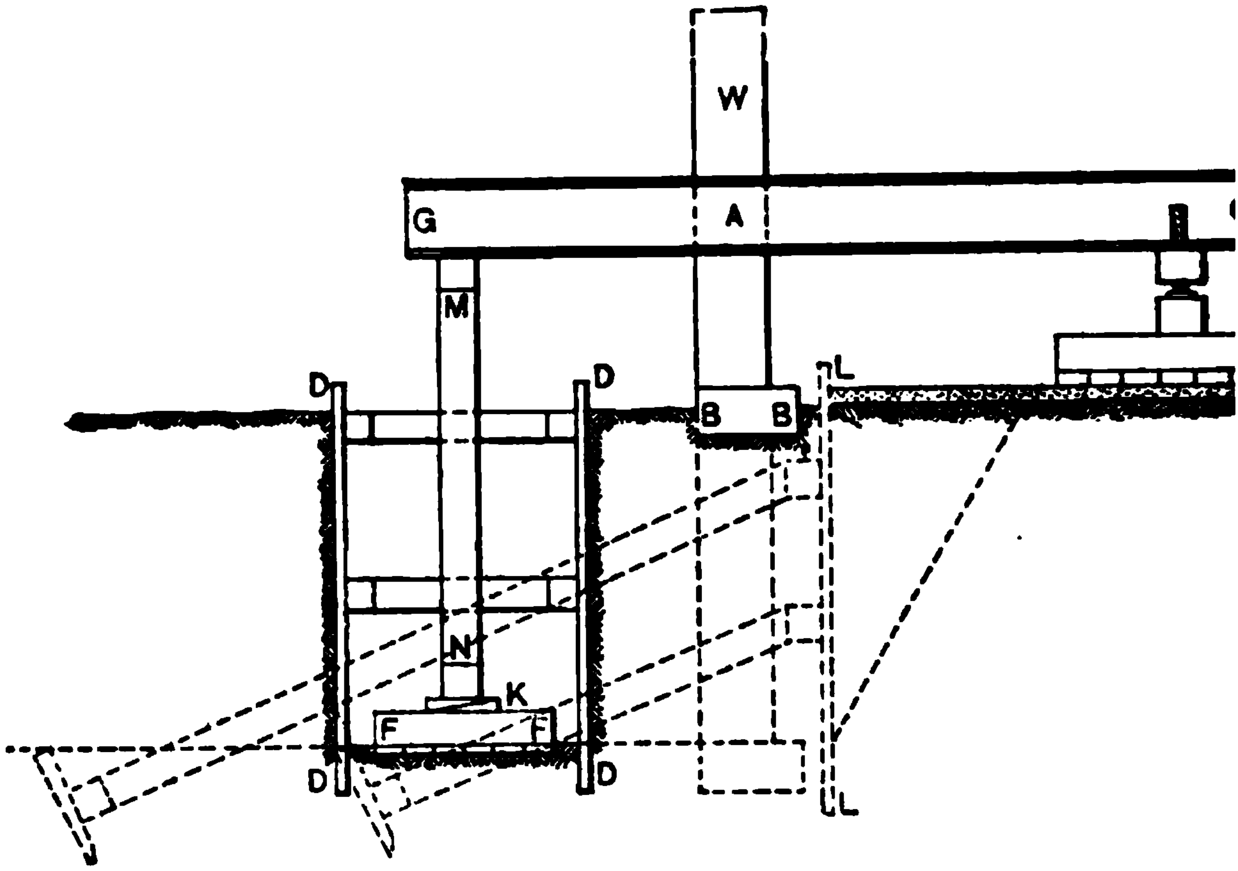

Fig. 51. Wall-needling and Underpinning

have this pit approach to within a few feet of the footing course of the w in material which is liable to run it should not approach the wall clos its depth. No hard and fast rule can be given, and in every case gr should be taken to prevent any movement of the material from under joining footing.

(3) **The Platforms.** On the bottom of this pit-excavation, a PLATF is placed, generally composed of heavy timbers resting on a base o planks, and acting as a support for the outer end of the needle. Du construction of this pit a similar pit may be dug on the inside of the wal vide for the support of the inside end of the needle; but as this invol destruction of the cellar-floor the method of procedure inside the bui generally different from this. If the material is solid it is sometimes s to place the platform for the support of the inside end of the needle on the cellar-floor and at such a distance from the wall that the n excavation for the new footing will not disturb it; or the platform placed on the cellar-floor and a line of sheeting *LL*, properly braced, so that the excavation can be made for the new footing. This is generally s to prevent any serious settlement of the temporary platform for the in of the needle.

[The] Insertion of the Needles. Having provided a support for each end [of the ne]edles it only remains to cut a hole through the wall, as at *A*, insert the [needle] *GG*, put the post and blocking *MN* under the outside end of the needle, [and th]e blocking and jacks under the inside end. The post *MN* may be fitted [with we]dges as shown at *K*, or with one or more screw-jacks. The needle *GG* [may con]sist of one or more heavy timbers or one or more steel I beams. In any [case th]e load to come on this needle should be figured and its strength made [sufficien]t to safely support such load. As soon as the weight of the wall *W* is [transfer]red to the needles and to the temporary platforms prepared to receive [it], that part of the wall which is below the needles and all of the foot[ings ma]y be removed and all of the excavation for the new footing made.

the footing is removed. The hanging parts of the wall may be removed pended by rods and chains to the needles. If they are not so susp crack will form along the line *AAAAA*.

Transferring the Load to the New Underpinning. As soon as footing has been put in place and the new wall carried up ready to rec old wall, provision must be made for REVERSING THE OPERATION, tha transferring the load onto the new underpinning wall and footing. generally done by means of a number of GRANITE BLOCKS set in pairs the needles and fitted with STEEL WEDGES. After setting these blocks, t between the base of the old wall and the top of the upper wedging block in with brickwo mortar in the la being compacted b of PIECES OF SLAT in so as to we mortar between th This brickwork sh laid up in Portland mortar so as to re time of setting. as it is sufficiently wedges are driven as to throw at leas tion of the weigh wall on the new As a result of thi quently happens t footing settles, t being restored needles. This nec continued driving wedges until it has its final settlemen will be evidenced b ing of the wall suff partially relieve th in the needles and fact that the we main tight.

Fig. 53. The Figure-four Method of Needling

Removal o Needles, etc. as the entire weigh wall has been tr to the footing and the footing has demonstrated that it is capable porting the weight of the wall without further settlement, all of the te work, including the needles, can be removed, the needle-holes bricked the repairs made to the cellar of the adjoining building.

The Figure-Four Method of Needling. In certain cases it is im to employ a NEEDLE-BEAM projecting on both sides of the wall, as for when the occupancy of the adjoining building is such as to make it im to have a needle-beam projecting into the cellar space. In such cases called FIGURE-FOUR NEEDLE has been employed (Fig. 53). In this needle *AB* acts as a CANTILEVER. Part of the load of the wall is carrie

Fig. 54. The Spring-needle Method of Underpinning

tending to lift the needle-beam acts on both walls, but on account of its [illegible]located nearer to the wall to be lifted, a large proportion of its effect is [illegible] thereon.

[illegible] or Cylinders for Underpinning are frequently used for the support [illegible] wall and have many advantages, as they not only afford a support for the [illegible] through the operations affecting the stability of the wall, but also form [illegible]ment support. The operation in brief is as follows: A hole or niche is [illegible] the wall and footing to be supported, of sufficient size to permit the intro[illegible] of a section of STEEL PIPE, in such manner that the center of the pipe [illegible] below the center of the wall to be supported, the height being sufficient [illegible]commodate a section of pipe and also the means employed to drive it. [illegible] pipe may be driven (1) by HYDRAULIC JACKS or by SCREW-JACKS, placed [illegible] the top of the pipe and the wall itself, as by the patented BREUCHAUD [illegible]; (2) it may be driven by means of a POWER-HAMMER driven either by [illegible] compressed air; or (3) in some cases, where the material is fine sand or [illegible] the pipe may be JETTED or the JET-METHOD may be used in combination [illegible] either jacks or power-hammers. In any case the first section of pipe is [illegible] into the ground and additional sections are added until the lower end of [illegible] encounters rock or some material possessing sufficient stability to insure [illegible] required support. The material entering the pipe is removed by a WATER-[illegible] by other means and the space filled with concrete. As soon as the con[illegible] set sufficiently the pipe is capped with a special casting on which short [illegible] beams are arranged to distribute the support of the pipe over a consider[illegible] of the base of the wall to be supported These I beams correspond

to the wedging blocks used in the ordinary methods before described.] vision is frequently made for STEEL WEDGES between the cap and the base of steel beam, but it is generally found sufficient to thoroughly grout in the between the base of the wall and the steel beams after the niche itself has bricked up.

Cylinders for Underpinning Very Heavy Walls. The description i preceding paragraph is intended to cover the use of pipes varying in size 6 to 20-in in diameter, according to the load to be carried. In the case of e sively heavy walls, CAST-IRON CYLINDERS are used in place of steel pipes. cylinders are arranged in sections, each section making a water-tight joint the preceding section, and are generally used where water is encountered where it is necessary to carry down the underpinning to rock at great de Under such conditions these cylinders are sunk by the PNEUMATIC-CA METHOD. Such cylinders have been sunk to a depth of 70 ft below water and have been designed to carry as much as 400 tons.

CHAPTER III

...NRY WALLS. FOOTINGS FOR LIGHT BUILDINGS.* CEMENTS AND CONCRETES

BY
THOMAS NOLAN
...SOR OF ARCHITECTURAL CONSTRUCTION, UNIVERSITY OF PENNSYLVANIA

1. Footings for Light Buildings

...ing Courses in General.† Every foundation or bearing wall overlying ...ing except solid rock should rest on a footing or base projecting beyond ...l on each side. On wet or very compressible soils these footings may be ...f steel beams or of reinforced concrete, as described in Chapter II, but ...nably firm soils and for buildings of moderate size and weight the foot-...re generally of concrete, stone, or brick. Footings answer two important ...es:

By distributing the weight of a structure over a larger area of bearing ...l, the pressure per square foot on the foundation-bed is diminished and ...ndency to vertical settlement correspondingly lessened.

By increasing the area of the base of a wall, footings add to its stability ...rm a protection against the danger of the work being thrown out of ...by any forces that may act on it. Nearly every building law requires ...very foundation wall or pier and every cellar or basement wall or pier ...ave a footing at least 12 in wider, that is, 6 in on each side, than the thick-...f the wall or pier, and this may be considered as the minimum projection, ...t in rare instances where there may be a special reason for making it less. ...n soils and for comparatively light buildings a projection of 6 in on each ...f a wall will generally reduce the unit pressure, that is, the pressure per ...foot, to the safe resistance of the soil, but it is always wise to proportion ...otings to a uniform unit pressure, as explained in Chapter II, Subdivision ...o have any useful effect, footings must be well bedded and have sufficient ...erse strength to resist the upward reactions on the projections.

...e Footings for Walls with Ordinary Loads. Stone cellar walls and ...ent walls generally have stone footings, although if the walls are heavily ...l a bottom footing of coarse concrete is advisable under the stone footing. ...ticable, stone footings should consist of stones having a width equal to ...f the footing. If impracticable to obtain stones of this size, then two ...should be used, meeting under the middle line of the wall. In any event ...ting course should extend inside of the course above, a distance equal to ...t one and one-half times the projection, otherwise the stones will not ...ly transmit the loads and reactions and the footing courses will tend to ...t the joints, as in Fig. 1.

...r a complete discussion of foundations in general and the mechanical principles ...d in their strength and stability, for walls, piers, etc., below the basement or ...ler, see Chapter II.

...r a complete discussion of footing courses for heavy buildings and of the theories ...resses developed in offset, projecting, or cantilever footings, see Chapter II. ...ly Subdivisions 17 to 23.

Stone footings should be of hard, strong and durable stones, always their natural bed and solidly bedded in mortar. As a general rule, f buildings, and where the loads per unit of foundation-bed are much le the allowable pressure, the thickness course is made about equal to its pr beyond the course above. The mo mon defect in large-stone footings the stones are not properly bedded, more difficult to bed a large stone small one. The stones should be la thick bed of mortar and worked sidew a bar until firmly settled in place.

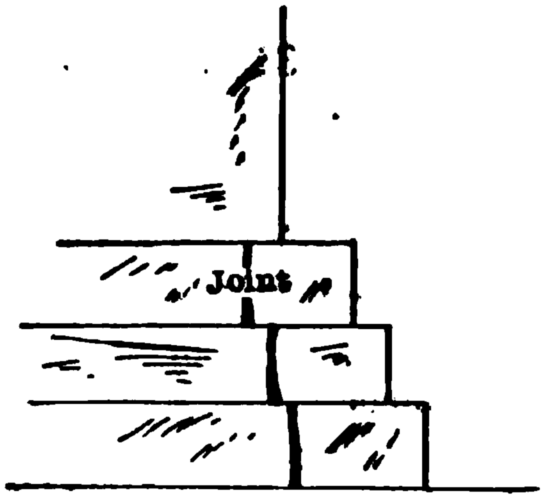

Fig. 1. Stone Footing. Openings at Joints

Offsets in Masonry Footings. projections of the footing courses the wall or beyond the courses abov be carefully considered, whatever t terial of the footings. If the proje the footing or offset of the courses great for the strength of the stone, brick, or concrete, the footing wil as shown in Fig. 2. The proper offset for each course depends u vertical load, the transverse strength of the material, the resisting power of the foundation-bed and the thickness of the course.†

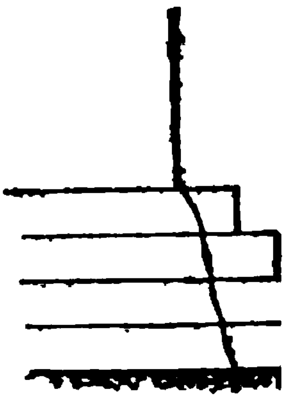

Fig. 2. Crack in from Excessive C

Tables for Offsets for Masonry Footing Courses.‡ As stated in Chapter II, in the discussion of the design of stepped footings, there are rule-of-thumb methods giving so-called safe projections for given depths of footings or giving the ratios between the projections and the depths of the courses. Tables of offsets for footing courses of different materials have been computed from the flexure-formula applied to the projecting footing courses considered as CANTILEVER BEAMS uniformly loaded by the upward pressures on the un Although these tables, so computed, are incorporated in some buildin they cannot be safely used without numerous restrictions, exceptions an fications, and hence they are, in general, unreliable and of use only as mations. As these tables are still inserted in engineers' and architect books, the table of offsets for masonry footing courses, in a revised for tained in this chapter with the recommendation that for footings of offsets it be used with caution and that for such footings the methods e in Chapter II be used when greater accuracy of results is required.

Notes Regarding Use of Table I. The values in Table I are co from the formula $l = \frac{1}{6} d \sqrt{S_f/wf}$ which is derived from the FLEXURE-F for a uniformly loaded cantilever beam, and slightly changed to m numerical coefficient of the second member of the equation the value In this equation, l = the maximum allowed offset of the footing course in d = the thickness of the footing course in inches, S_f = the modulus of

* See Offset Footings, Chapter II, especially Subdivisions 17 and 22.

† See Chapter II, Subdivision 22, for a complete discussion of the principles in the design of projecting footings, ratio of projection to depth of footing, etc., geneous slabs, separate-layer footings, etc.

‡ See Chapter II, Subdivision 22, page 180.

§ See, also, formula in Chapter II, Subdivision 22.

ble I. Approximate Values of Offsets for Masonry Footing Courses in Terms of the Thickness of the Course

The values are computed with a factor of safety of 10.

Material of the footings	S_f in pounds per square inch	w in tons per square foot 0.5	1.0	2.0
rth River Bluestone (ordinary run)	3 000	4.1	2.9	2.0
anite (average)	1 850	3.2	2.2	1.6
mestone (average)	1 375	2.8	2.0	1.4
ndstone (average)	1 375	2.8	2.0	1.4
ickwork (good bricks in natural-cement mortar, 1:2, 60 days old)	125	0.8	0.6	0.4
ickwork (hard-burned bricks in Portland-cement mortar, 1:3, 60 days old)	400	1.6	1.1	0.7
ncrete (Portland cement, 1 : 2 : 4, 1 month old)	300	1.3	0.9	0.6
ncrete (Portland cement, 1 : 2 : 4, 6 months old)	400	1.6	1.1	0.7

the materials in pounds per square inch, w = the determined or assumed sure on the bottom surface of the footing course considered, in tons of 2 000 per sq ft, and f = the factor of safety used. The table gives the values of l/d three unit pressures w. For example, if w is taken at 2 tons per sq ft, then limestone or sandstone footings l/d = 1.4, and if d, the thickness of the ing course, is 12 in, the offset or projection should be 16 or 17 in. The es given in the table for S_f, the modulus of rupture for the materials, differ slightly from those given in Subdivision 22 of Chapter II, in Table I of pter XV and in Table III of Chapter XVI. If results are required based different fiber-stresses, upon a different factor of safety, or upon different sures per square foot, the formula may be used instead of the table. It ld always be borne in mind that as each footing course transmits the entire ht of the wall and its load, the pressure will be greater per square foot on upper courses, and that the offsets should be made proportionately less; that the values in Table I, when applied to stone-masonry footings, are y valid for the lower offset only, and then only when the footing is built nes the thickness of which is equal to the thickness of the course, which e a projection of less than half their length, and which are well bedded in nt mortar.

ncrete Footings.* For buildings of great weight, except the very heaviest, especially for those built on a clay soil, concrete generally makes the best ing, and it is even preferable to and generally cheaper than large slabs of e. When the concrete is properly made and used, it attains a strength l to that of most stones, and under walls, being devoid of joints, it is like tinuous BEAM, having sufficient strength to span any soft spots that pen to be in the foundation-bed. When deposited in thin layers and well ed, concrete becomes firmly bedded on the bottom of the trenches, so that e is no possible chance for settlement except that due to the compression of oil.

* For an example of concrete-footing design, see Chapter II, Subdivision 22. For ed-concrete-footing design, see Chapter II, Subdivision 24. See, also, Chapter paragraphs relating to footings, pages 978 to 982.

Preparing the Trenches. For footings, concrete made with Po cement is preferable, and it should have a thickness of at least 8 in, even light buildings; and for buildings of more than two stories, a thickness least 12 in. On firm soils, such as hard clay, the trenches should be accu dug and trimmed to the exact width of the footings, so that the concret fill them. When the foundation-bed is of loose gravel or sand it is gen necessary to set up planks to confine the concrete and form the sides footings. These planks may be held in place by stakes; they should b in place until the concrete has become hard, which generally requires fro to four days, after which they may be pulled up and dirt filled in again concrete. The proportions and manner of mixing concrete are described latter part of this chapter.

Depositing the Concrete. Concrete should be used as soon as mixe should always be deposited in layers, which as a rule should not exceed 6 thickness, especially for the first layer. On small jobs where the work i by hand the concrete is usually carried to the trenches in wheel-barrow dumped into the trenches. The height from which the concrete is du however, should not exceed 4 ft above the bottom of the trench, because w falls from a greater height the heavy particles are apt to separate fro lighter ones. As soon as the concrete has been deposited in the trenc should be leveled off and then tamped with a wooden rammer weighing 20 lb, until the water in the concrete is brought to the surface. Concrete not be permitted to dry too quickly, and if twenty-four hours elapse be the deposits of the successive layers, the top of each layer should be spr before the next is put in place. For buildings over five stories high, it is idea to place a stone footing course above the concrete footing, if suitable for the purpose can be obtained.

Brick Footings. Where the foundation walls are of bricks, the footi usually brick or concrete. For interior walls on dry ground, and in

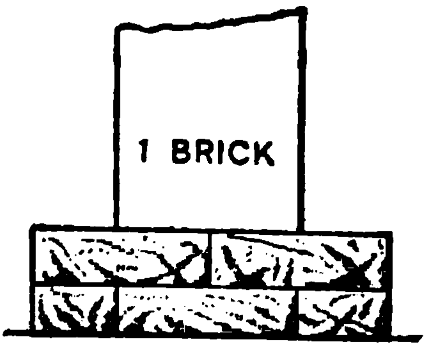

Fig. 3. Brick Footing. Wall One Brick Thick

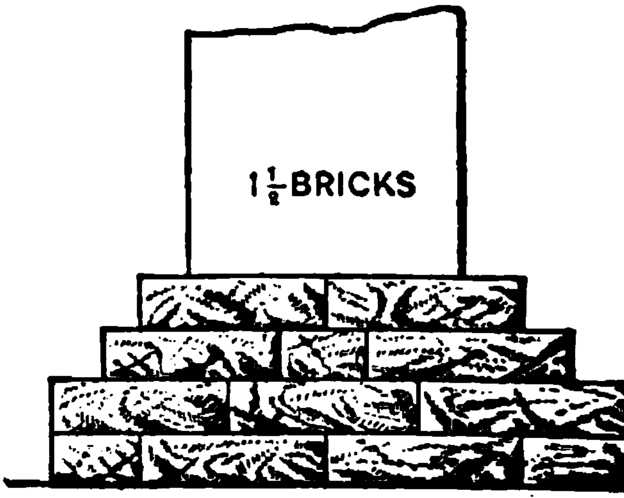

Fig. 4. Brick Footing. Wall One One-half Bricks Thick

localities for outside walls, brick footings are fully as good as stone fo provided good, hard bricks are used and the footings are properly built. footings should always start with a DOUBLE COURSE on the foundation-b then be laid in single course for ordinary footings, the outside of the wor laid all HEADERS, as in the accompanying illustrations, and no course pro more than one-fourth the length of a brick beyond the one above it, ex the case of an 8-in or 9-in wall. For brick footings under high or heavily walls, each projecting course should be made double, the HEADER-COURSE and the STRETCHER-COURSE below. Figs. 3, 4, 5 and 6 show footings fo

ing from one brick to three bricks in thickness. The bricks used for footshould be the hardest and soundest that can be obtained, should be laid in t mortar and should be either grouted or thoroughly slushed up, so that joint shall be entirely filled with mortar. The writer favors GROUTING brick footings, that is, the g of a thin mortar to fill the e joints, as he has always d that it gives very satisfacresults. The bottom course the footing should always be in a bed of mortar spread the bottom of the trench the latter has been carey leveled. All bricks laid in m or dry weather should be oughly wet before laying, for, laid dry, they rob the mortar a large percentage of the mois-

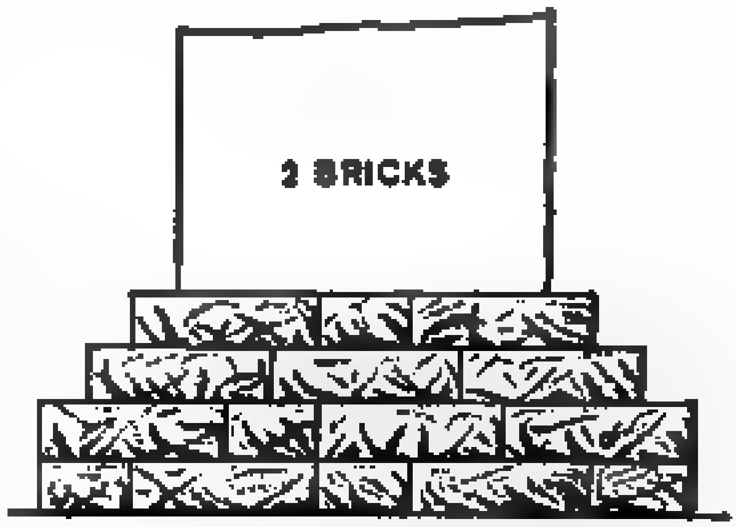

Fig. 5. Brick Footing. Wall Two Bricks Thick

it contains, greatly weakening the adhesion and strength of the mortar. ful attention should be given to the laying of the footing courses of ings, as upon them the stability of the work largely depends. If the m courses are not solidly bedded, if any rents or voids are left in the of the masonry, or if the materials themselves are unsound or badly

Fig. 6. Brick Footing. Wall Three Bricks Thick

together, defects in the superstructure are almost sure to show themp sooner or later, and almost always at a period when remedial efforts are ult and expensive.

erted Arches.* In a few buildings in which the external walls are ded into piers with wide openings between them, and in which the supportwer of the soil is not more than 2 or 3 tons per sq ft, it was thought desirconnect the bases of the piers by means of INVERTED ARCHES, for the purf distributing the weight of the piers over the whole length of the footings. les of inverted-arch footings are shown in Figs. 7 † and 8,† which represent ively the construction employed in the Drexel Building in Philadelphia

r an example worked out in full, showing the method of proportioning inverted see Chapter III, Building Construction and Superintendence, Part I, Masons' y F. E. Kidder.

m the Engineering Record, May, 1899, and Nov., 1890.

and the World Building in New York City. Unless the piers are about eq loaded, however, it is generally impossible to distribute the weight evenly if the arches extend to an angle of the building, the end-arch must be pro with ties of sufficient strength to resist the THRUST of the arch, as otherw may push out the corner-pier. It is usually better to build the piers with rate footings, projecting equally on all sides of the pier, and each proport

Fig. 7. Inverted-arch Footing. Drexel Building, Philadelphia

Fig. 8. Inverted-arch Footing. Building, New York

to the load supported. The intermediate wall may be supported by steel or by arches. About the only advantage over ordinary masonry fo possessed by inverted arches is in the resulting shallower foundations.

The following, relating to inverted arches, is taken from the New York ing law: "If, in place of a continuous foundation wall, isolated piers are built to support the superstructure, where the nature of the ground ar character of the building make it necessary, in the opinion of the Commis of Buildings having jurisdiction, inverted arches resting on a proper b concrete, both designed to transmit with safety the superimposed loads, be turned between the piers. The thrust of the outer piers shall be tak by suitable wrought-iron or steel rods and plates." (Law of 1906.)

2. Cellar Walls and Basement Walls

Definitions. These terms are generally applied to walls which are the surface of the ground or below the water-table or first-floor l which support the superstructure and which go down to the FOUNDATION v properly so called. (See Chapter II, Divisions 1 and 29.) Walls whose office is to withhold a bank of earth, such as the walls around areas, are RETAINING-WALLS. (For retaining-walls, see Chapter IV.)

Materials for Cellar and Basement Walls. These walls may be b brick, stone or concrete. BRICK is suitable only in very dry soils or for a wall with a cellar or basement on each side of it. PORTLAND-CEMENT CON is an excellent material for foundation walls, and is being more exte used in their construction every year. The concrete may be filled in b wooden forms, which hold it in place until it has set, or concrete blocks s so as to form a solid wall may be used. If POURED CONCRETE is used the

... be removed as soon as the concrete has set and the walls should be ... once or twice a day, if the weather is dry, so that the concrete will not ... quickly Good hard LEDGE-STONE, especially if it comes from the quarry ... flat beds, makes not only a strong wall but, if well built, one that will stand ... effects of moisture and the pressure of the earth much better than a brick ... Between a good stone wall and a wall of Portland-cement concrete, ... is probably not much choice, except perhaps in the matter of expense, the ... relative cost of stonework and concrete varying in different localities. A wall ... of soft stones, or stones that are very irregular in shape, with no flat surfaces, ... greatly inferior to a concrete wall, or even to a wall of good hard bricks, and ... should be used only for dwellings or light buildings. Stone walls should never ... less than 18 in thick, and should be well bonded, with full and three-quarter ... headers, and all spaces between the stones should be filled solid with mortar ... broken stones or spalls. The MORTAR for stonework should be made of ... cement and sharp and rather coarse sand. The outside walls of cellars ... basements should be PLASTERED smooth on the outside with 1 : 2, or 1 : 1½ ... cement mortar, from ½ to ¾ in thick. In heavy-clay soils it is a good idea to ... the walls on the outside, making them from 6 in to 1 ft thicker at the ... than at the top.

Thickness of Cellar and Basement Walls. This is usually governed by ... of the walls above, and also by the depth of the wall. Nearly all building ... regulations require that the thickness of the cellar and basement wall, to the ... depth of 12 ft below the grade-line, shall be 4 in greater than the thickness of the ... above for bricks, and 8 in greater for stone, and that for every additional ... or part thereof in depth, the thickness shall be increased 4 in. In all large ... the thickness of the walls of buildings is controlled by law. For buildings ... which the thickness of the walls is not so governed, the following table will ... as a guide:

Table II. Thickness of Cellar and Basement Walls

	Brick, in	Stone, in	Brick, in	Stone, in
... stories	12 or 16	20	16	20
... stories	16	20	20	24
... stories	20	24	24	28
... stories	24	28	24	28
... stories	28	32	28	32

2. Walls of the Superstructure

Brick and Stone Walls. Very little is known regarding the STABILITY of ... of buildings beyond what has been gained by practical experience. The ... stresses in any horizontal sections of such walls, which can be determined ... any accuracy, are the direct weight of the walls above and the pressure ... the floors and roof. In most walls, however, there is a tendency to ..., to overcome which it is necessary to make them thicker than would ... required to resist the DIRECT CRUSHING STRESS. The resistance to fire should ... taken into account in deciding upon the thickness of any given wall.

The strength of a wall depends also very much upon the quality of the m used and upon the way in which the wall is built. A wall bonded ever in height, and with every joint slushed full with good rich mortar, is as as a poorly built wall 4 in thicker. Walls laid with cement mortar a much stronger than those laid with lime mortar, and a brick wall bui bricks that have been well wet just before laying is very much stronger th built with dry bricks.

Thickness of External Walls. In nearly all the larger cities of the c the minimum thickness of the walls is prescribed by law or ordinance, these requirements are generally ample they are commonly adhered to by tects when designing brick buildings. Table III * gives the thickness o walls required for MERCANTILE BUILDINGS in representative cities of di sections of the United States, and affords about as good a guide as o have, because the values given, as a rule, represent the judgment o qualified and experienced persons. Walls for DWELLINGS are generall mitted to be 4 in less in thickness than for warehouses, although in cities little or no distinction is made between business blocks and dwelli

Table IV gives the thickness required for the brick walls of dwellings ments, hotels and office-buildings † in Chicago. The thickness given is th mum that should be allowed for the walls of such buildings, unless special conditions exist. For modifications for different classes of buildi the building code. In St. Louis the two upper stories of dwellings are r to be 13 in, the next two below, 18 in, the next two 22 in, and the next tw thick.

In compiling Table III the top of the second floor was taken at 19 ft the sidewalk, and the height of the other stories at 13 ft 4 in, includi thickness of the floor, as the New York and Boston laws and the laws o other cities give the height of the walls in feet instead of in stories. W height of stories exceeds these measurements the thickness of the walls i cases will have to be increased. The Chicago ordinance (1916) specifi "where 12-in walls are used, the story-heights shall not exceed 18 ft, whe walls are used, the story-heights shall not exceed 24 ft, and where 20-i are used, the story-heights shall not exceed 30 ft."

General Rule for Thickness of Walls. Although there are great ences in the thickness given in Table III, more indeed than there sho a general rule might be formulated from it, for MERCANTILE BUILDIN four stories in height, which would be somewhat as follows:

For bricks equal to those used in Boston or Chicago, make the thick the three upper stories 16 in, of the next three below 20 in, the next thr and the next three 28 in. For a poorer quality of material make only t upper stories 16 in thick, the next three 20 in, and so on down. In buildi than five stories in height the top story may be 12 in thick.

In determining the thickness of walls the following general principles be recognized:

(1) That walls of warehouses and mercantile buildings should be than those used for living or office purposes.

* Since this table was compiled, some provisions of some laws have been chan the requirements relating to the thicknesses of walls vary but little from thos As building laws of different cities are amended from time to time, architects and must be guided by the code in force in the city in which a building is to be erecte table represents the average requirements and is useful for comparative purpose a guide for those building outside of cities, or where no special building laws are

† For other than steel skeleton construction.

† These thicknesses are allowed when certain requirements are fulfilled in re[illegible] ngths of walls, heights of stories, etc. For these modifying restrictions and [illegible]assifications of buildings in regard to their uses the building laws must be co[illegible] he table is inserted in this form as a useful general guide and as an illustratio[illegible] verage contemporary practice. For modifications for different classes of buildi[illegible] de.

‡ For other than steel skeleton construction.

That high stories and clear spans exceeding 25 ft require thicker

That the length of a wall is a source of weakness, and that the thickness be increased 4 in for every 25 ft over 100 or 125 ft in length. In New the thicknesses given in the table must be increased for buildings exceeding ft in depth on the lot. In Western cities the tables are compiled for 125 ft in depth, as that is the usual depth of lots in those

That walls with over 33% of openings should be increased in thickness. That partition walls may be 4 in less in thickness than the outside walls over 60 ft long, but that no partition should be less than 8 in thick.

Faced with Ashlar. "Bearing walls faced with ashlar shall be at least thick. Ashlar shall not be included in reckoning the thickness of walls it is either at least 8 in thick or alternately 4 in and 8 in to allow at least bond. Ashlar not having at least a 4-in bond in alternate courses must be the backing by metal anchors, one to each block 3 ft or less long, and each block over 3 ft long." *

Walls should generally be 4 in thicker than required for brick

Walls. Hollow walls are undoubtedly desirable for dwellings, and be used for other buildings not more than four or five stories in height, of the security afforded from the weather. Owing to the fact that are usually more expensive than solid walls and occupy more space, they very extensively used in this country.

Boston building law requires that vaulted walls shall contain, exclusive the same amount of material as is required for solid walls, and the on the inside of the air-space in walls over two stories in height shall less than 8 in thick, and the parts on either side shall be securely tied with ties not more than 2 ft apart in each direction.

of Concrete Blocks. Blocks made of Portland-cement concrete, and in molds, are frequently used for building walls and partitions that are thin and bear light loads. Patents have been taken out on forms of blocks and on machines or processes for making the same. buildings have been erected with walls built of these blocks. Most of are molded so as to form hollow walls. Block construction of this an advantage over poured walls, in that the blocks are thoroughly before they are set and hence no provision is required for expansion or For the thin, light walls above mentioned the concrete-block is better adapted than solid concrete. The expense of forms is and also the tendency to crack and to leave an unsatisfactory surface. Concrete blocks may be substituted for any ordinary stone or brick. Building laws usually require the thickness of walls of hollow con- to be not less than that required for brick walls. They should not in party walls. (See, also, Chapter XXIII, Subdivision 2.)

of Hollow Tiles. Hollow tiles are used for the external walls of and sometimes for factories in some locations and under certain For example, the building laws (1913) of the District of Columbia hollow tiles, not less than 12 in in thickness, to be used for the

* Boston Building Law, in force in 1915.

external walls of dwellings located not less than 3 ft from the side or pa of the lot. The Philadelphia laws do not allow the use of hollow tiles external wall or heavy bearing partition. As far as fire-resistance is con construction of hollow tiles is, of course, superior to wooden construction, use is increasing, the outside walls being usually covered with cement or although occasionally left with the finished texture of the tile surface reason hollow tiles are prohibited by building ordinances for certain because when heated and then suddenly cooled by water they are apt t from the sudden contraction. Recent conflagrations have shown tha burned terra-cotta will crack and fall to pieces under severe heat alone. also, Chapter XXIII, Subdivision 2.)

Party Walls. There is much diversity in building regulations re the thickness of party walls, although they all agree in that such walls never be less than 12 in thick. About one-half of the laws require th walls shall be of the same thickness as external walls; the remainder ar equally divided between making the party walls 4 in thicker or thinn for independent side walls. When the walls are proportioned by previously given the author believes that the thickness of the party wall be increased 4 in in each story. The floor-load on party walls is o twice that on side walls, and the necessity for thorough fire-prote greater in the case of party walls than in other walls.

Enclosing Walls for Steel, Skeleton Construction. In building skeleton type the outer masonry walls are usually supported either i story or every other story by the steel framework, and carry nothing b own weight. Such walls may, therefore, be considered as only one stories high, and are usually made only 12 in thick for the whole hei twelve-story or fifteen-story building. For SKELETON CONSTRUCTI Chicago ordinance allows ENCLOSING WALLS of 12-in thickness for all The former New York City code* required the use of 12-in enclosing wal ft of the uppermost height thereof, or to the nearest tier of beams to that ment, and 4 in additional thickness for every lower 60-ft section or to t est tier of beams to such vertical measurement, down to the tier of bea est to the curb-level. But, on account of the severity of some of the ments as applied to very high buildings of skeleton construction, pe was frequently given by the Commissioners of Buildings, who were em to modify the building laws within certain limits, to reduce the thi of certain walls for very high buildings, according to the peculiar circum of each case, without endangering the strength and safety of the A few of the earlier tall buildings were built with SELF-SUSTAINING starting from the foundation, while columns were introduced merely to the floors and to give additional stiffness. "The World Building, N City, erected in 1890, is an extreme example of high-building cons with self-sustaining walls. The main roof is 191 ft above the str making thirteen main stories, above which is a dome containing six s all, a height of 275 ft above the street. The self-sustaining walls are sandstone, brick and terra-cotta, the thickness increasing from 2 ft a to as much as 11 ft 4 in near the bottom, where the walls are offset to a footing 15 ft wide. The walls are vertical on the outside faces, the being varied by inside offsets, so that the columns are recessed into at the bottom, but emerge and are some distance clear of the walls at t

* The revised Code, 1916-17, allows 12-in curtain walls in skeleton buildings height of building, when supported on girders in each story. This practice i by about fifty other cities.

† From Architectural Engineering, by J. K. Freitag.

4. Natural Cements and Mortars*

perties and Uses of Natural Cements. The first hydraulic cements in this country were NATURAL CEMENTS, manufactured by the calcination ...laceous limestone containing sufficient silica, alumina and iron oxide to ... hydraulic properties when the burned rock was pulverized and gauged ... water. These natural cements were very widely manufactured and used ... recent years, when they have been practically completely replaced by ...and cement. Natural cements vary in color from light yellow to dark ... according to the content of oxide of iron, and in distinction to Portland ...ts they are not uniform in their composition or behavior. The chemical ...sition and physical characteristics of various natural cements vary within ...imits, not only between cements manufactured in different mills, but be- ... the products of the same mill at different times. Natural cements set ... rapidly than Portland cements and are slower in developing strength. ...production of natural cement in the United States for 1913 was 800 000 ...s, while during the same year the production of Portland cement was ...000 barrels; from which it is seen that the natural-cement industry is ...ely almost extinct. Natural cement may be used in massive masonry ... weight rather than strength is the essential feature. It is used, also, ...rtain special purposes, such as in the manufacture of safes and in certain ...tries where a quick-setting cement is necessary. Where economy is the ...ing factor, a comparison may be made between the use of natural cement ... leaner mixture of Portland cement that will develop the same strength.

...ight. The specifications of the American Society for Testing Materials ...e that a bag of natural cement shall contain 94 lb, net, of cement, and that ... barrel of natural cement shall contain three bags of this NET WEIGHT.

...ength. A natural-cement mortar, in order to comply with the require- ...s of the standard specifications of the American Society for Testing Ma- ...s, must show a TENSILE STRENGTH, for the neat cement, of at least 150 lb ... in, when one week old, and 250 lb at the end of 28 days; or, when mixed ... three parts of standard Ottawa sand, 50 lb at the end of one week, and 125 ... the end of 28 days. The strength of 1 : 2 natural-cement mortar is about ... to that of 1 : 4 Portland-cement mortar.

...portions of Natural Cement and Sand for Mortar and Concrete. ...ortar for rubble-stone masonwork and ordinary brickwork, one part of ...l cement may be mixed with three parts of sand, by measure.

...draulic Lime. A product closely related to natural cement is HYDRAULIC ... This is manufactured in the same way as natural cement, but the rock ...contains sufficient lime to permit it to slake like quicklime. When the ...ing product is pulverized, it sets and hardens as an hydraulic cement. ...ulic limes are largely manufactured in Europe, and especially in France ...elgium, but in the United States they have been manufactured only in a ...alities. This is due to the fact that while rock of suitable composition ...ly found, the impurities are not uniformly distributed through it, but are ... in layers or seams which prevent the material from being uniformly ...d. The portion of the rock immediately adjacent to and including the ...f impurities overburns, frequently melting like a slag, while the purer ...s consist simply of quicklime; and while the resulting mass slakes partly, ...duct when pulverized is unreliable as a cement.

* ...tical data relating to Cements, Limes and Plasters were furnished the Editor by ...les Warner Company of Wilmington, Del. For Limes and Plasters, see Part ...es 1548 to 1558.

Grappier Cement is a BY-PRODUCT produced during the calcination DRAULIC LIME.

La Farge Cement is an imported NON-STAINING GRAPPIER CEME develops nearly the same strength as the Portland cements.

5. Artificial Cements and Mortars

The Artificial Cements used in the United States include Portland and Puzzolan or slag cement.

Portland Cement. The principal artificial cement in this countr is PORTLAND CEMENT. It is manufactured from two raw materials wl ground to extreme fineness to secure an intimate mix before burning, is from this fact that it derives its name, ARTIFICIAL CEMENT. Th terials must be so proportioned that in the finished cement, silica, alumi oxide and lime will be present in a certain ratio which must be mai within close limits. In the Lehigh Valley region of Pennsylvania, i are located some of the leading Portland-cement mills of the United St raw materials used are limestone and cement-rock. The cement-rock i pure limestone carrying argillaceous or clay-matter. In order to bring t content up to the required percentage, it is usually found necessary region to add limestone. In other districts the raw materials used a stone and clay, limestone and shale, marl and clay and also blast-furn and limestone. The product from the last-mentioned mixture shoulc confused with the common slag cement or Puzzolan cement, as the slag i used as a raw material supplying silica, alumina, iron oxide and lime; a the exception of the use of slag to furnish these ingredients, the process o facture and the properties are substantially the same as for the other I cements. The raw mix in a Portland cement mill is analyzed at mc several times each hour to keep the composition of the cement within th limits. The raw material, which is pulverized as fine as the finished ce burned in rotary kilns, the fuel used in most instances being powder From the kiln it issues in the form of CLINKER, the name given to the rified product. After cooling, calcium sulphate in the form of gy added to control the set and the product is pulverized and packed for sh The manufacture and properties of Portland cement have been made the of careful study by the American Society for Testing Materials and American Society of Civil Engineers. The result of this study is emb the standard specifications of the American Society for Testing Mate tracts from which are given in the paragraphs following. These speci furnish a reliable guide for the acceptance or rejection of any shipmer ment and have been very widely adopted by the leading architects and e of this country. These specifications do not stipulate that Portland cem consist of any one particular composition, but in this respect confine th to the limitation of the magnesia (MgO) and anhydrous sulphuric acid (S tent. The reason for this is that with different raw materials it is foun sary to vary the composition of the cement to obtain the correct properties in the finished material. Different cements which satisfy the ments of these standard specifications are generally considered satisfac ments for use, although the composition of one may vary in some pa from that of another. The CHEMICAL COMPOSITION of a good brand land cement is about as follows: Lime, 62; silica, 23; alumina, 8; and im such as iron oxide, magnesia, and sulphuric acid, 7.

STANDARD SPECIFICATIONS FOR PORTLAND CEMENT.* The following give the most important requirements for Portland cement:

* From the Standard Specifications and Tests for Portland Cement, revised, fective, January 1, 1917), by the American Society for Testing Materials.

(1) DEFINITION. Portland cement is the product obtained by finely pulveriz- clinker produced by calcining to incipient fusion an intimate and properly pro- portioned mixture of argillaceous and calcareous materials, with no additions sub- sequent to calcination excepting water and calcined or uncalcined gypsum. (2) CHEMICAL LIMITS. The following limits shall not be exceeded:

Loss on ignition, per cent	4.00
Insoluble residue, per cent	0.85
Sulphuric anhydride (SO_3), per cent	2.00
Magnesia (MgO), per cent	5.00

(3) SPECIFIC GRAVITY. The specific gravity of cement shall be not less than (3.07 for white Portland cement). Should the test of cement as received fall below this requirement a second test may be made upon an ignited sample. The specific-gravity test will not be made unless specifically ordered. (4) FINENESS. The residue on a standard No. 200 sieve shall not exceed 22 per cent by weight. (5) SOUNDNESS. A pat of neat cement shall remain firm and hard, and show no signs of distortion, cracking, checking, or disintegration in the steam test for soundness. (6) TIME OF SETTING. The cement shall not develop initial set in less than 45 minutes when the Vicat needle is used, or 60 minutes when the Gillmore needle is used. Final set shall be attained within 10 hours. (7) TENSILE STRENGTH. The average tensile strength in pounds per square inch of not less than three standard mortar briquettes composed of 1 part cement and 3 parts standard sand, by weight, shall be equal to or higher than the following:

Age at test, days	Storage of briquettes	Tensile strength, lb per sq in
7	1 day in moist air, 6 days in water	200
28	1 day in moist air, 27 days in water	300

(8) The average tensile strength of standard mortar at 28 days shall be higher than the strength at 7 days. (9) PACKAGES AND MARKING. The cement shall be delivered in suitable bags or barrels with the brand and name of the manu- facturer plainly marked thereon, unless shipped in bulk. A bag shall contain 94 lb net. A barrel shall contain 376 lb net. (10) STORAGE. The cement shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weather-tight building which will protect the cement from dampness. (11) INSPECTION. Every facility shall be provided the purchaser for careful sampling and inspection at either the mill or at the site of the work, as may be specified by the purchaser. At least 10 days from the time of sampling shall be allowed for the completion of the 7-day test, and at least 31 days shall be allowed for the completion of the 28-day test. The cement shall be tested in accordance with the methods hereinafter prescribed. The 28-day test shall be waived only when specifically so ordered. (12) REJEC- TION. The cement may be rejected if it fails to meet any of the requirements of these specifications.

Sections (13) to (15), also, relate to Rejection. (See complete Specification.)

Puzzolan or Slag Cements are not used extensively and never in important work. Their manufacture and properties may be briefly described as follows: Blast-furnace basic slag is granulated by running it in a molten condition into water. This accomplishes two objects. The slag is broken up into fine particles and the sudden chilling enhances its hydraulic properties. These particles are dried and ground with hydrated lime, in the proportion of from 15 to 25% hydrated lime and from 75 to 85% of granulated slag. Such cement, known as SLAG CEMENT, is slow-setting and slow-hardening, and does not develop as

much strength as natural or Portland cement. Slag cements are characte by their light lilac color, their extreme fineness and their low specific gra They are considered unreliable for use except for foundation-work under gr where they are not exposed to air or running water.

Stainless Cements. Any ordinary Portland or natural cement will limestones, some porous marbles, some granites and some other light-co stones. The best non-staining material is lime, that is, lime free from exce iron oxide. There are some Portland cements, however, which are called STAINING CEMENTS, and where care is used in their manufacture and the free or comparatively free from iron oxide, they cause no trouble. Ar the non-staining cements which have been extensively used for masonr which staining would be objectionable, is La Farge Cement, before mentic It is made at Teil, France, is light-colored and contains a small percenta iron and soluble salts. There are other non-staining cements on the ma For setting stones, and in order to RETARD THE SETTING of the cement unti stones are well bedded, 1 part by volume of lime-paste is usually mixed 4 parts of the cement.

Cost of Portland Cement.* Portland cement can now (1915) be purch in this country at prices ranging from 90 cents to $2.50 per barrel, free on b cars at the mills. The cost of the sacks and the freight are extra. The r price for single barrels varies from about $2.00 to $2.50 per barrel. As a the cost of cement in carload lots is about 85 cts per bbl at the mills. An e charge of 10 cts per bbl for bags is made when the cement is delivered in p bags. The extra charge is 40 cts, if delivered in cloth, but the mills refund 40 cts when the bags are returned in good condition. There is a charge c cts when the cement is furnished in wooden barrels and no allowance is r for barrels returned. It is generally cheaper in the end to buy the ceme cloth bags and return the empty bags. For about 500 miles, the fre charges are about 40 cts per bbl of cement, making the total cost per bb this distance $1.25, when purchased in cloth bags and when the 40 cts per are refunded. Testing costs from 3 to 5 cts per bbl, or from $5 to $6 carload. Unloading and storing near the station cost about 3 cts per bbl, about 2 cts per bbl are usually added to the costs to allow for handling returning empty sacks, and freight-charges for and damage to same. Tea costs about 5 cts per bbl per mile. The total cost, therefore, accordin these average costs, is about $1.38 per bbl for the cement ready for us mortar or concrete. (For Cost of Concrete, see page 249; also foot-note for s

Water Required in Mixing Cement Mortar. Good Portland ce requires relatively little water to make a good mortar. Neat cement will from 20 to 22% (by weight) of water to produce the normal consistenc quick-setting cement requiring more water than one that is slow-setting. greater quantity of water is required, it indicates the presence of an exce free lime. When sand is mixed with cement, in the proportion of 3 to 1, more than from 9 to 12½% (by weight) of water will be required. Na cements and slag cements require more water than do Portland cements. much water drowns the cement, retards the setting and weakens the mo Cements can also be weakened or even spoiled by a deficiency of water.

Portland-Cement Mortar. For first-class mortar not more than 3 b sand should be added to 1 bbl of cement. For rubble stonework under ordi conditions a mortar composed of 4 parts of sand to 1 of cement will answer e purpose, and be much stronger than lime mortar. For the top surface of f

* See foot-note, page 249.

alks, from 1 to 1½ parts of sand may be mixed with 1 part of cement. 3 Portland-cement mortar has about the same strength at the end of one as 1 to 1 natural-cement mortar. Mortar made with fine sand requires a larger quantity of cement to obtain a given strength than mortar made with se sand. (See page 276 for ideal mortar with hydrated lime for brickwork.)

ects of Low Temperatures and Freezing on Cement Mortars. The of setting and hardening of cement mortar is greatly affected by the temper-e, and the exposure and loading of new work often depends upon the pre-ing temperature. The freezing of natural-cement mortars should be en-y avoided as it seriously injures them. Although freezing greatly retards hardening of Portland-cement mortars and concretes, it does not appear injure them. Thin coats of mortar, such as plaster, and troweled surfaces se on which free moisture is formed should not be applied in freezing ther as they are apt to scale. In general, it is undesirable to work with tar or concrete in freezing weather, as the difficulties of properly mixing placing the materials are then increased; it must be admitted, however, t successful work with Portland-cement mortar and concrete has been done emperatures considerably below freezing.

he Effect of Salt in Mortar. When salt is added to the water of mix-g, the freezing-point is lowered, and, within certain limits, the freezing of mortar or concrete is prevented. The ultimate strength of mortar does not ar to be reduced when the amount of salt does not exceed 10%. Tetmajer s the amount of salt required to lower the freezing-temperature as equal to of the weight of the water per degree F. below 32°. The rule for the pro-tion of salt used in the works at Woolwich Arsenal, is said to have been as ws: "Dissolve 1 lb of rock-salt in 18 gal of water when the temperature is 2° F., and add 3 oz of salt for every three degrees of lower temperature."

ffect of Hot Water and of Soda. Hot water hastens the setting of tland-cement mortar, and 2 lb of carbonate of soda in 1 gal of water, boiled mixed in mortar, hastens the setting and lessens the danger of freezing.

uantity of Mortar required for Masonry and Plastering.* "One bbl Portland cement and 3 bbl of sand, thoroughly and properly mixed, will ke 3¼ bbl, or 12 cu ft of good strong mortar. This will be sufficient to lay 1½ cu yd of rough stone, or about 750 bricks, with from ¼ to ⅜-in joints, over 125 sq ft of surface, 1 in thick, or 250 sq ft, ½ in thick."

"One bbl of natural cement and 2 bbl of lime, mixed with about ½ bbl of er, will make 8 cu ft of mortar, sufficient to lay 522 common bricks, with ¼ to ⅜-in joints, or about 1 cu yd of rough rubble."

For the top coat of walks or floors, 1 bbl of Portland cement and 1 of sand cover from 75 to 80 sq ft, ½ in thick, or from 50 to 56 sq ft, ¾ in thick. One bbl of Portland cement and 1½ bbl of sand will cover from 110 to 120 sq f floor, ½ in thick, or from 75 to 80 sq ft, ¾ in thick.

he Mixing of Mortar. Mortar may be mixed by hand or by mechanical ers, the latter being preferable for the mixing of large quantities. When mixing is by hand, it should be done on platforms made water-tight to pre-t the loss of cement. The cement and sand should be mixed dry in small ches and in the proportions required, the platform being clean. Water is ed and the whole mass remixed until it is homogeneous and leaves the mixing clean when drawn out. Mortar should never be retempered after it has n to set.

*These figures can be considered as approximate only, as the amount of mortar will y on different jobs.

Adhesive Strength of Portland Cement, Sulphur and Lead for Anc ing Bolts.* "Fourteen holes were drilled in a ledge of solid limestone, s of them being 1¾ and seven 1⅝ in in diameter, and all being 3½ ft deep. S ¾ and seven 1-in bolts were prepared with thread and nut on one end and the other end plain but ragged for a length of 3½ ft.

"Four were anchored with sulphur, four with lead and six with cem mixed neat. Half the number of the ¾-in and 1-in bolts being thus anchored each of the three materials, all stood until the cement was two weeks Then a lever was rigged and the bolts pulled, with the following results.

"Sulphur: Three bolts out of four developed their full strength 16 000 31 000 lb. One 1-in bolt failed by drawing out, under 12 000 lb. Lead: T bolts out of four developed their full strength, as above. One 1-in pulled out, under 13 000 lb. Cement: Five of the bolts out of six broke w out pulling out. One 1-in bolt began to yield in the cement at 26 000 lb, sustained the load a few seconds before it broke.

"While this experiment demonstrated the superiority of cement, both a strength and ease of application, it did not give the strength per square inc area. To determine this, four specimens of limestone were prepared, 10 in wide, 18 in long and 12 in thick, two of them having 1¾-in holes, and of them 2¾-in holes drilled in them. Into the small holes 1-in bolts w cemented, one of them being perfectly plain round iron, and the other havi thread cut on the portion which was embedded in the cement. Into the 2¾ holes were cemented 2-in bolts similarly treated, and the four specimens w allowed to stand 13 days before completing the experiment. At the end of time they were put into a standard testing-machine and pulled. The plain bolt began to yield at 20 000 lb and the threaded one at 21 000 lb. The plain bolt began to yield at 34 000 lb and the threaded one at 32 000 lb, force in all cases being very slowly applied. The pump was then run at a gre speed, and the stones holding the 2-in bolts split at 67 000 lb in the case of smooth one and at 50 000 lb in the case of the threaded one.

"It is thus seen that for anchoring bolts in stone, cement is more relia stronger and easier of application than either lead or sulphur, and that its sistance is from 400 to 500 lb per sq in of surface exposed. It is also a w ascertained fact that it preserves iron rather than corrodes it. The cem used throughout the experiment was an English Portland cement."

8. Concrete †

Properties and Uses of Concrete.‡ There is probably no material th so enduring or better adapted for foundations, walks and basement floors, than cement concrete, and for certain classes of buildings it is used with vantage for the walls, floors and interior supports. There are now thousand buildings in this and other countries in which all of the structural portions formed of reinforced concrete, and the use of Portland-cement concrete f

* The test of these materials is reported in the American Architect, page 105, xxiv.

† The subject of concrete in general, including plain or mass-concrete and reinfo concrete, is to-day so important, and the available data so vast in amount that only t brief statements of general principles and of the best engineering practice that are the i important for the architect and builder to know can be included in a handbook of kind. For full treatments of the subject, the readers are referred to the numerous re treatises, tests, proceedings of engineering societies, etc.

‡ For reinforced Concrete, see Chapter XXIV; for Concrete Foundations, Chapte for Reinforced-Concrete Factory Construction, Chapter XXV; and for Strength of C crete, Chapter V. See, also, Chapter XXIII, pages 817 and 843.

riety of purposes is rapidly extending, due to the reduced price of d cement, and to a better appreciation and understanding of its proper- merits. Concrete may be defined as an artificial stone, made by cement, water and what is called an aggregate, consisting of small and rticles of sand or screenings and gravel or broken stone; and when with good Portland cement, in proper proportions, it becomes so hard that when pieces of it are broken, the line of fracture often passes the particles of stone, showing that the adhesion of the cement to the is greater than the cohesive strength of the stone itself.

Aggregates.* "Extreme care should be exercised in selecting the aggre- for mortar and concrete, and careful tests made of the materials for the e of determining their qualities and the grading necessary to secure m density or a minimum percentage of voids. A convenient coefficient ity is the ratio of the sum of the volumes of materials contained in a lume to the total unit volume. (See, also, pages 908 and 909.)

Fine Aggregates should consist of sand, crushed stone, or gravel screen- aded from fine to coarse and passing when dry a screen having ¼-in diam it preferably should be of siliceous material, and should be clean, coarse, m dust, soft particles, vegetable loam or other deleterious matter, and re than 6% should pass a sieve having 100 meshes per lin in. Fine aggre- hould always be tested. Fine aggregates should be of such quality ortar composed of one part Portland cement and three parts fine aggre- y weight when made into briquettes will show a tensile strength at least to the strength of 1 : 3 mortar of the same consistency made with the ement and standard Ottawa sand. This is a natural sand obtained at a, Ill., passing a screen having 20 meshes and retained on a screen having hes per lin in. It is prepared and furnished by the Ottawa Silica Com- for 2 cts per lb, free on board cars, at Ottawa, Ill., under the direction of ecial Committee on Uniform Tests of Cement of the American Society l Engineers. If the aggregate be of poorer quality the proportion of t should be increased in the mortar to secure the desired strength. If ngth developed by the aggregate in the 1 : 3 mortar is less than 70% of ngth of the Ottawa-sand mortar, the material should be rejected. To he removal of any coating on the grains, which may affect the strength, nds should not be dried before being made into mortar, but should con- tural moisture. The percentage of moisture may be determined upon a e sample for correcting weight. From 10 to 40% more water may be d in mixing bank or artificial sands than for standard Ottawa sand to e the same consistency.

Coarse Aggregates should consist of crushed stone or gravel which is d on a screen having ¼-in diam holes and graded from the smallest to est particles; they should be clean, hard, durable and free from all ous matter. Aggregates containing dust and soft, flat or elongated s should be excluded from important structures."

kind of stone is suitable for the coarse aggregate which has such strength e strength of the concrete is not limited by the strength of the stone. trength is of little advantage beyond this minimum. The stones gener- ployed are granites, traps and limestones. Shales and sandstones of

* of the matter of this paragraph, and of following paragraphs relating to concrete, of data and conclusions formulated by the joint committees of the Am. Soc. C. E., for Test. Mats., Am. Ry. Eng. and Maint. of Way Asso., and Asso. of Am. Cement Manfrs. In regard to Aggregates, etc., see, also, the same subjects in XXIV, pages 908 and 909, and foot-notes on page 908 in that chapter.

deficient strength should be tested before use. Screened gravel generally a good coarse aggregate. "The maximum size of the coarse aggregate is g by the character of the construction. For reinforced concrete and fo masses of unreinforced concrete, the aggregate must be small enough to with the mortar a homogeneous concrete of viscous consistency which readily between and easily surround the reinforcement and fill all parts forms. For concrete in large masses the size of the coarse aggregate increased, as a large aggregate produces a stronger concrete than a fi although it should be noted that the danger of separation from the becomes greater as the size of the coarse aggregate increases."

The use to be made of the concrete determines the maximum size of th aggregate. When used in mass-concrete construction, such as heavy the maximum size may run up to 2½ and 3 in with good results. For rei work and thin walls, however, it is necessary to reduce the maximum s in or less. It has been found that the following are the maximum sizes coarse aggregate of plain or mass-concrete in the best practice: for foun 2½ in; for abutments, 2 in; for arch-rings, 1¼ in; and for copings, thi etc., 1 in.

"Cinder concrete should not be used for reinforced-concrete structu may be allowable in mass for very light loads or for fire-protection p The cinders used should be composed of hard, clean, vitreous clinkers, fi sulphides, unburned coal, or ashes. (See, also, page 909.)

"**Water for Mixing Concrete.** The water used in mixing concrete be free from oil, acid, alkalies, or organic matter."

Preparing and Placing Mortar and Concrete. "(1) **Proportions** materials to be used in concrete should be carefully selected, of uniform and proportioned with a view to securing as nearly as possible a m density.

"(a) Unit of Measure. The unit of measure should be the cubic f bag of cement, containing 94 lb, net, should be considered the equival cu ft. The measurement of the fine and coarse aggregates should be volume.

"(b) Relation of Fine and Coarse Aggregates. The fine and coars gates should be used in such relative proportions as will insure maxim sity. In unimportant work it is sufficient to do this by individual ju using correspondingly higher proportions of cement; for important wo proportions should be carefully determined by density-experiments sizing of the fine and coarse aggregates should be uniformly maintaine proportions changed to meet the varying sizes.

"(c) Relation of Cement and Aggregates. For reinforced-concr struction, one part of cement to a total of six parts of fine and coars gates, measured separately, should generally be used. For column mixtures are generally preferable, and in massive masonry or rubble a mixture of 1 : 9 or even 1 : 12 may be used. These proportions sh determined by the strength or the wearing-qualities required in the c tion at the critical period of its use. Experienced judgment based on in observation and tests of similar conditions in similar localities is an guide as to the proper proportions for any particular case. For all in construction, advance tests should be made of concrete, of the materi portions and consistency to be used in the work. These tests should under laboratory conditions to obtain uniformity in mixing, proportio

* See, also, in Chapter XXIV, paragraphs relating to these subjects on and foot-note relating to the same, on page 908 of that chapter.

and in case the results do not conform to the requirements of the work, [...]s of a better quality should be chosen or richer proportions used to [...] the desired results."

[...] Turneaure of the University of Wisconsin gives the following as [pro]portions of cement, sand and coarse aggregate generally used for various [kinds] of work:

[Re]inforced columns and structural parts [req]uiring extra strength..................	from 1 : 1 : 2 to 1 : 1½ : 3
[For] buildings, thin walls, reinforced concrete, [...]s and impervious construction.........	from 1 : 2 : 4 to 1 : 2½ : 4½
[For] structures requiring great strength rather [tha]n mass..............................	from 1 : 2½ : 5 to 1 : 3 : 6
[For] structures requiring mass rather than [str]ength, foundations, etc..................	from 1 : 3 : 6 to 1 : 4 : 8

[...] **Mixing Concrete.** The ingredients of concrete should be thoroughly [mixed] and the mixing should continue until the cement is uniformly distributed [and the] mass is uniform in color and homogeneous. As the maximum density [and gr]eatest strength of a given mixture depend largely on thorough and com[plete mi]xing, it is essential that the work of mixing should receive special atten[tion an]d care. Inasmuch as it is difficult to determine, by visual inspection, [whethe]r the concrete is uniformly mixed, especially where limestone or aggre[gates ha]ving the color of cement are used, it is essential that the mixing should [continue for] a definite period of time. The minimum time will depend on whether [the mix]ing is done by machine or hand.

[...] **Measuring Ingredients.** Methods of measurement of the proportions [of the] various ingredients should be used which will secure separate and uni[form] measurements of cement, fine aggregate, coarse aggregate and water at [all ti]mes.

[...] **Machine-Mixing.** When the conditions will permit, a machine-mixer [of a ty]pe which insures the uniform proportioning of the materials throughout [the ma]ss should be used, as a more uniform consistency can be thus obtained. [The m]ixing should continue for a minimum time of at least one minute after [all the] ingredients are assembled in the mixer.

[...] **Hand-Mixing.** When it is necessary to mix by hand, the mixing should [be on] a water-tight platform and especial precautions should be taken to turn [the] ingredients together at least six times and until they are homogeneous in [appear]ance and color."

[Th]e most satisfactory method * of mixing concrete by hand is to first prepare [for] mixing of the materials, a tight floor of planks, or, better still, of sheet [iron wi]th the edges turned up about 2 in. Upon this platform should first be [spread] the sand, and upon this the cement. The two should then be thoroughly [and im]mediately mixed by means of shovels or hoes until of an even color. [The] water should be added to make a thin mortar which is then spread [...] The gravel, if used, should then be added, and then the broken stone. [The] stone should be first thoroughly wet, if originally dry. The mass [should] be turned until all the ingredients are thoroughly incorporated and all [the ston]e and gravel covered with mortar, this requiring from four to six turn[ings].

[...] **Consistency.** The materials should be mixed wet enough to result in a [concrete] of such a consistency that it will flow into the forms and about the metal [reinfor]cement when used, and which, at the same time, can be conveyed from

* This paragraph is condensed from several recent specifications.

the mixer to the forms without separation of the coarse aggregate fi mortar.

"(e) Retempering. Mortar or concrete should not be remixed wit after it has partly set."

(3) **Placing Concrete.** "(a) Methods. Concrete after the compl the mixing should be handled rapidly, and in as small masses as is pra from the place of mixing to the place of final deposit, and under no stances should concrete be used that has partly set. A slow-setting should be used when a long time is likely to occur between mixing and Concrete should be deposited in such a manner as will permit the most t compacting, such as can be obtained by working with a straight shovel o tool kept moving up and down until all the ingredients have settled proper places by gravity and the surplus water has been forced to the Special care should be exercised to prevent the formation of LAITANCE, hardens very slowly and forms a poor surface on which to deposit fresh c All LAITANCE should be removed. When suspended work is resum crete previously placed should be roughened, thoroughly cleansed of material and laitance, thoroughly wetted and then slushed with a mor sisting of one part Portland cement and not more than two parts fine ag The faces of concrete exposed to premature drying should be kept w period of at least seven days."

"(b) Mixing and Depositing Concrete in Freezing Weather. (should not be mixed or deposited at a freezing temperature, unless spe cautions are taken to avoid the use of materials covered with ice-cr containing frost, and to provide means to prevent the concrete from after being placed in position and until it has thoroughly hardened. coarse aggregate forms the greater portion of the concrete, it is par important that this material be heated to well above the freezing-point.

"(c) Rubble Concrete. Where the concrete is to be deposited in work, its value may be improved and its cost materially reduced by th clean stones thoroughly embedded in the concrete and as near togetl possible while still entirely surrounded by concrete.

"(d) Depositing Concrete Under Water. In placing concrete under is essential to maintain still water at the place of deposit. The use of T properly designed and operated, is a satisfactory method of placing through water. The concrete should be mixed very wet (more so tha dinarily permissible) so that it will flow readily through the tremies the places with practically a level surface. The coarse aggregate sh smaller than ordinarily used, and never more than 1 in in diameter. Tl gravel facilitates mixing and assists the flow of concrete through the The mouth of the tremie should be buried in the concrete so that it times entirely sealed and the surrounding water prevented from forci into the tremie; the concrete will then discharge without coming in with the water. The tremie should be suspended so that it can be quickly when it is necessary either to choke off or prevent a too rapid f

* Laitance is a whitish, gelatinous substance of about the same composition but with little tendency to harden. It accompanies a disintegration of so cement from the surface of concrete which is exposed to the action of water i is deposited. The concrete is thus weakened and the laitance, also, weakens between old and new material and should be removed before fresh concrete is

† A tremie is a round or square box or tube of wood or plate iron open at th bottom. The diameter varies from 12 to 24 in. The tremie rests in the depo crete, extends above the water-level and is kept full of concrete, which escap bottom as the tube is shifted over the surface.

[illegible] flow should preferably be not over 15 ft. The flow should be continuous [illegible] to produce a monolithic mass and to prevent the formation of laitance [illegible] interior. In large structures it may be necessary to divide the mass of [illegible] into several small compartments or units, filling one at a time. With [illegible] care it is possible in this manner to obtain as good results under water as [illegible] air."

[illegible] for Concrete. "Forms should be substantial and unyielding, so that [illegible] concrete will conform to the designed dimensions and contours, and should [illegible] tight in order to prevent the leakage of mortar. The time for removal of forms [illegible] of the most important considerations in the erection of a structure of con[illegible] or reinforced concrete. Care should be taken to inspect the concrete and [illegible] its hardness before removing the forms. So many conditions affect [illegible] hardening of concrete, that the proper time for the removal of the forms [illegible] be decided by some competent and responsible person, especially where [illegible] atmospheric conditions are unfavorable. It may be stated, in a general [illegible] that forms should remain in place longer for reinforced concrete than for [illegible] massive concrete, and that the forms for floors, beams and similar hori[illegible] structures should remain in place much longer than for vertical walls. [illegible] the concrete gives a distinctive ring under the blow of a hammer, it is [illegible] an indication that it has hardened sufficiently to permit the removal [illegible] forms with safety. If, however, the temperature is such that there is [illegible] possibility that the concrete is frozen, this test is not a safe reliance, as [illegible] concrete may appear to be very hard."

[illegible] Shrinkage of Concrete and Temperature-Changes. "Shrinkage of con[illegible], due to hardening and contraction from temperature-changes, causes [illegible], the size of which depends on the extent of the mass. The resulting [illegible] are important in monolithic construction and should be considered care[illegible] by the designer; they cannot be counteracted successfully, but the effects [illegible] minimized. Large cracks produced by quick hardening or wide ranges [illegible] temperature can be broken up to some extent into small cracks by placing [illegible] in the concrete; in long continuous lengths of concrete, it is [illegible] to provide shrinkage-joints at points in the structure where they will do [illegible] no harm. Reinforcement is of assistance and permits longer distances [illegible] shrinkage-joints than when no reinforcement is used. Small masses or [illegible] bodies of concrete should not be joined to larger or thicker masses without [illegible] for shrinkage at such points. Fillets similar to those used in metal [illegible], but of larger dimensions, for gradually reducing from the thicker to [illegible] thinner body, are of advantage. Shrinkage-cracks are likely to occur at [illegible] where fresh concrete is joined to that which is set, and hence in placing [illegible] concrete, construction-joints should be made on horizontal and vertical [illegible] and, if possible, at points where joints would naturally occur in dimen[illegible] masonry."

[illegible] Effect of Heat on Concrete Fireproofing.* "The actual fire-tests of [illegible] and reinforced concrete have been limited, but experience, together [illegible] the results of tests thus far made, indicates that concrete, on account of [illegible] rate of heat-conductivity and the fact that it is incombustible, may be [illegible] safely for fireproofing purposes. The dehydration of concrete probably [illegible] at about 500° F. and is completed at about 900° F.; but experience indi[illegible] that the volatilization of the water absorbs heat from the surrounding mass, [illegible] together with the resistance of the air-cells, tends to increase the heat-[illegible] of the concrete, so that the process of dehydration is very much re-

* See, also, Chapter XXIII, page 817.

tarded. The concrete that is actually affected by fire remains in positi affords protection to the concrete beneath it. The thickness of the pro coating required depends on the probable duration of a fire which is lil occur in the structure and should be based on the rate of heat-condu The question of the conductivity of concrete is one which requires furthe and investigation before a definite rate for different classes of concrete fully established. However, for ordinary conditions it is recommende the metal in girders and columns be protected by a minimum of 2 in crete; that the metal in beams be protected by a minimum of 1½ in of co and the metal in floor-slabs be protected by a minimum of 1 in of co It is recommended that in monolithic concrete columns, the concrete to a of 1½ in be considered as protective covering and not included in the ef section. It is recommended that the corners of columns, girders and be beveled or rounded, as a sharp corner is more seriously affected by fire round one."

Waterproofing Concrete. "Many expedients have been used to concrete impervious to water under normal conditions, and also under pr conditions that exist in reservoirs, dams and conduits of various kinds. rience shows, however, that where mortar or concrete is proportioned to the greatest practicable density and is mixed to a rather wet consisten resulting mortar or concrete is impervious under moderate pressure. crete of dry consistency is more or less pervious to water, and compou various kinds have been mixed with the concrete, or applied as a wash surface for the purpose of making it water-tight. Many of these com are of but temporary value, and in time lose their power of imparting im ability to the concrete. In the case of subways, long retaining-walls and voirs, provided the concrete itself is impervious, cracks may be so redu horizontal and vertical reinforcement properly proportioned and locate they are too minute to permit leakage or are soon closed by infiltration Coal-tar preparations applied either as a mastic or as a coating on felt or fabric are used for waterproofing, and should be proof against injury by or gases. For retaining-walls and similar walls in direct contact wi earth, the application of one or two coatings of hot coal-tar pitch to th oughly dried surface of concrete is an efficient method of preventing the tration of moisture from the earth." (See, also, Waterproofing for F tions, Part III.

Surface-Finish of Concrete. "Concrete is a material of an individu and should not be used in imitation of other structural materials. One important problems connected with its use is the character of the fi exposed surfaces. The finish of the surface should be determined befo concrete is placed, and the work conducted so as to make possible the desired. For many forms of construction the natural surface of the co is unobjectionable; but frequently the marks of the boards and the fla surface are displeasing, thus making some special treatment desira treatment of the surface either by scrubbing it while green or by tooling it is hard, which removes the film of mortar and brings the aggregates concrete into relief, is frequently used to remove the form-markings, bre monotonous appearance of the surface, and make it more pleasing. The p ing of surfaces should be avoided, for even if carefully done, the plaster is to peel off under the action of frost or temperature-changes."

Design of Massive Concrete. "In the design of massive or plain co no account should be taken of the tensile strength of the material, and s should usually be proportioned, so as to avoid tensile stresses, except in

...ts, to resist indirect stresses. This will generally be accomplished, in ...e of rectangular shapes, if the line of pressure is kept within the middle ...of the section, but in very large structures, such as high masonry dams, a ...exact analysis may be required. Structures of massive concrete are able ...ist unbalanced lateral forces by reason of their weight; hence the element ...ight rather than strength often determines the design. A relatively cheap ...weak concrete, therefore, will often be suitable for massive concrete struc... It is desirable generally to provide joints at intervals to localize the ...t of contraction. Massive concrete is suitable for dams, retaining-walls, ...piers and short columns in which the ratio of length to least width is rela...y small. Under ordinary conditions this ratio should not exceed six. It ...is suitable for arches of moderate span, where the conditions as to founda...s are favorable."

...uantities of Materials Required per Cubic Yard of Concrete.* The ...wing tables give the quantities of Portland cement required to make 1 cu yd ...ortar and the quantities of cement, sand and stone required to make 1 cu ...of concrete. They are based upon formulas deduced by Halbert P. Gillette.

Barrels of Portland Cement per Cubic Yard of Mortar

Voids in sand, 35%, 1 bbl of cement yielding 3.65 cu ft of cement paste

Proportion of cement to sand	1 to 1	1 to 1½	1 to 2	1 to 2½	1 to 3	1 to 4

...el specified to be 4.0 cu ft	4.00	3.24	2.73	2.36	2.08	1.54
...el specified to be 4.4 cu ft	3.81	3.07	2.57	2.27	2.00	1.40
...bic yard of sand per cu yd of mortar..............	0.6	0.7	0.8	0.9	1.0	1.0

Barrels of Portland Cement per Cubic Yard of Mortar

Voids in sand, 45%, 1 bbl of cement yielding 3.4 cu ft of cement paste

Proportion of cement to sand	1 to 1	1 to 1½	1 to 2	1 to 2½	1 to 3	1 to 4
	bbl	bbl	bbl	bbl	bbl	bbl
...el specified to be 3.5 cu ft	4.62	3.80	3.25	2.84	2.35	1.76
...el specified to be 3.8 cu ft	4.32	3.61	3.10	2.72	2.16	1.62
...el specified to be 4.0 cu ft	4.19	3.46	3.00	2.64	2.05	1.54
...el specified to be 4.4 cu ft	3.94	3.34	2.90	2.57	1.86	1.40
...bic yard of sand per cu yd of mortar..............	0.6	0.8	0 9	1.0	1.0	1.0

...n using these tables remember that the proportion of cement to sand is ...ume and not by weight. If the specifications state that a barrel of cement ...be considered to hold 4 cu ft, for example, and that the mortar shall be

*...uoted, by permission, from the Handbook of Cost Data for Contractors and En...., by Halbert P. Gillette, published by The Myron C. Clark Publishing Company, ..., Ill. See 1914 revised edition, pages 538 to 540. This handbook contains com...nd voluminous data on quantities, costs, etc., of building materials and operations.

1 part cement to 2 parts sand, then 1 bbl of cement is mixed with 8 cu ft of regardless of what is the actual size of the barrel, and regardless of how cement paste can be made with a barrel of cement. If the specifications state what the size of a barrel will be, then the contractor is left to guess.

"If the specifications call for proportions by weight, assume a Portlar ment barrel to contain 380 lb of cement, and test the actual weight of a foot of the sand to be used. Sand varies extremely in weight, due both variation in the per cent of voids, and to the variation in the kind of mi of which the sand is composed. A quartz sand having 35% voids weighs per cu ft; but a quartz sand having 45% voids weighs only 91 lb per cu the weight of the sand must be guessed at, assume 100 lb per cu ft. specifications require a mixture of 1 part of cement to 2 parts of sand, by w we will have 380 lb (or 1 bbl) of cement mixed with 2 times 380, or 760 sand; and if the sand weighs 90 lb per cu ft, we shall have 760 divided by 8.44 cu ft of sand to every barrel of cement. In order to use the tables given, we may specify our own size of barrel; let us say 4 cu ft; then, 8.44 di by 4 gives 2.11 parts of sand by volume to 1 part of cement. Without ma error we may call this a 1 to 2 mortar, and use the tables, remembering th barrel is now 'specified to be' 4 cu ft. If we have a brand of cement that 3.4 cu ft of paste per bbl and sand having 45% voids, we find that approxin 3 bbl of cement per cu yd of mortar will be required.

"It should be evident from the foregoing discussions that no table c made, and no rule can be formulated that will yield accurate results unle brand of cement is tested and the percentage of voids in the sand determ This being so, the sensible plan is to use the tables merely as a rough and, where the quantity of cement to be used is very large, to make a few b of mortar, using the available brands of cement and sand in the propo specified. Ten dollars spent in this way may save a thousand, even on a paratively small job, by showing what cement and sand to select."

Ingredients in One Cubic Yard of Concrete *

Sand-voids, 40%; stone-voids, 45%; Portland-cement barrel yielding 3.65 cu paste. Barrel specified to be 3.8 cu ft

† ...onditions changed many costs. Values given are retained temporarily for pur- ...f comparison.

are reduced for heavy mass-concrete, and have been as low as 50 or 60 cu yd for machine-mixing and placing together, by mixer and derrick tracks and cars. The following approximate schedule * of labor-costs fc ing and placing concrete is given by L. H. Allen of the Aberthaw Coı tion Company, in Professor Hool's excellent treatise:

For footings	\$1.50 per cu y
For floor-slabs not exceeding 4½ in in thickness	\$1.60 per cu y
For floor-slabs exceeding 5 in in thickness	\$1.00 per cu y
For columns and thin walls	\$1.50 per cu y
For walls exceeding 18 in in thickness	\$1.00 per cu y
For dams and thick retaining-walls	\$0.70 per cu y

For the unit cost due to the cost of the tools, plant and supplies, \$1 r taken as an average for jobs requiring from 4 000 to 10 000 cu yd of co It varies, of course, with the character and magnitude of the work. Tl for this item is reduced in larger jobs, falling to 80 or even 70 cts per and it is increased in operations of less magnitude to from \$1 to \$1.50 per for, say, 3 000 cu yd of concrete. When the amount of concrete require small as 600 or 700 cu yd, hand-mixing is generally more economica machine-mixing. Mr. Allen summarizes * the cost of 1 cu yd of concret building requiring 5 000 cu yd of reinforced-concrete work in floors and c as follows, the cost of forms and steel and finishing of the surface not included:

Cement, 1¾ bbl, at \$1.38 per bbl	\$2.
Sand, ½ cu yd, at \$1 per cu yd	0.
Stone, 1.35 tons, at \$1.40 per ton	1.
Labor, per cu yd	1.
Plant, per cu yd	1.
Total, per cu yd	\$7.

In this summary the exact theoretical proportions or quantities of sand and stone required for 1 cu yd of concrete, and deduced from fo are not adhered to, the author stating that the exact theoretical proporti the net quantities of the materials determined by careful experimen "conditions on actual construction work do not approach those of lab work and that there is always a considerable waste of cement, sand and In view of these facts, he states that, "when estimating quantities, it is to allow less than the following amounts of cement for different prop of mix:

1 : 1½ : 3 mix	2.00 bbl per cu yd
1 : 2 : 4 mix	1.66 bbl per cu yd
1 : 2½ : 5 mix	1.40 bbl per cu yd
1 : 3 : 6 mix	1.20 bbl per cu yd

It is customary to allow ½ cu yd of sand and 1 cu yd of crushed s 1 cu yd of concrete, and to estimate the weight of crushed stone at 10 cu ft.

The Weight of Concrete varies from 110 to 155 lb per cu ft, acco the material used. Concrete of the usual proportions weighs from 140 t per cu ft. Trap-rock concrete weighs from 148 to 155; limestone o concrete, from 142 to 148; and cinder concrete from 80 to 115 lb per cu

lier Examples of Portland-Cement Concrete. From the foregoing it n that for foundation-work to-day, mass-concrete varies in proportions a 1 : 3 : 6 to a 1 : 4 : 8 mix. Some of the earlier examples are added for parison.

undations of the United States Naval Observatory, Georgetown, D. C.: nt cement, 2½ sand, 3 gravel, 5 broken stone. (1 bbl of cement, 380 lb, le 1.18 yd of concrete.)

undations of the Cathedral of St. John the Divine, New York: 1 part and cement, 2 parts sand, 3 parts quartz gravel of pieces from 1½ to 2 in meter. (17 000 bbl of cement made 11 000 yd of concrete.)

lanhattan Life Insurance Building, New York, filling of caissons: 1 part n Portland cement, 2 parts sand, 4 parts broken stone.

leston Building (15 stories), New York, filling of caissons: 1 part Portland nt, 3 parts sand, 7 parts stone, finished on top for brickwork with 1 part nt and 3 parts gravel.

ofessor Baker states that the concrete foundations under the Washington ument were made of 1 part Portland cement, 2 parts sand, 3 parts gravel 4 parts broken stone, and that this mixture stood, when six months old, a l of 2 000 lb per sq in, or 144 tons per sq ft.

CHAPTER IV

RETAINING-WALLS, BREAST-WALLS AND VAULT-WALLS

By

GRENVILLE TEMPLE SNELLING

MEMBER OF AMERICAN INSTITUTE OF ARCHITECTS

1. Mechanical Principles Involved

General Principles. Before discussing more in detail the problems r to masonry structures, in which, if improperly constructed, a tendency t or overturn on their bases may be developed, a familiarity with what are as the THEOREM OF FRICTION and the THEOREM OF THE MIDDLE THIRD of assistance in comprehending the methods indicated for rendering such tures stable.

Theorem of Friction. If a body rests on an inclined plane it will stationary until the angle ϕ, that the plane makes with the hori

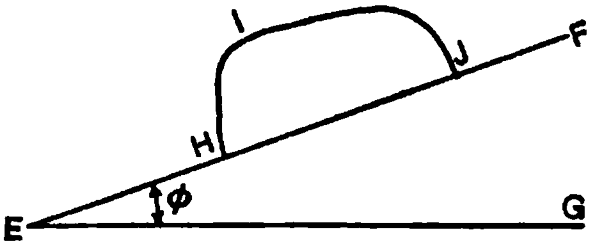

Fig. 1

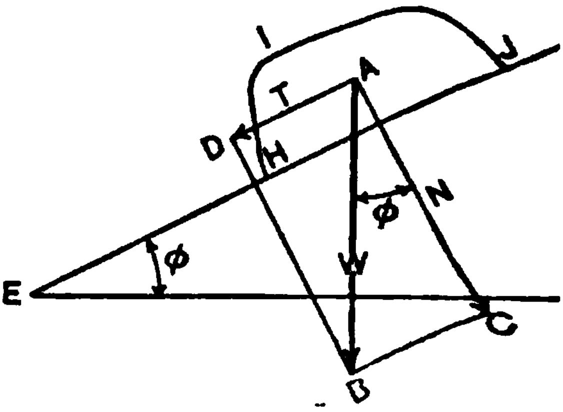

Fig. 2

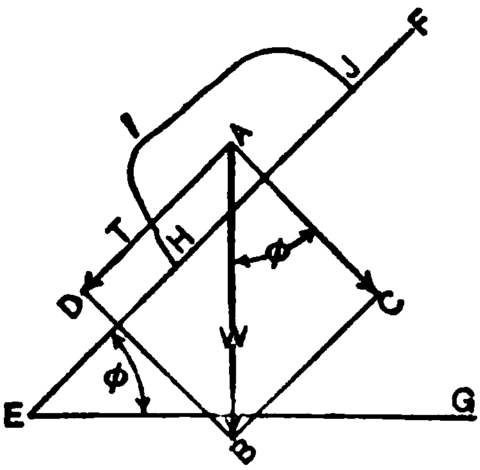

Fig. 3

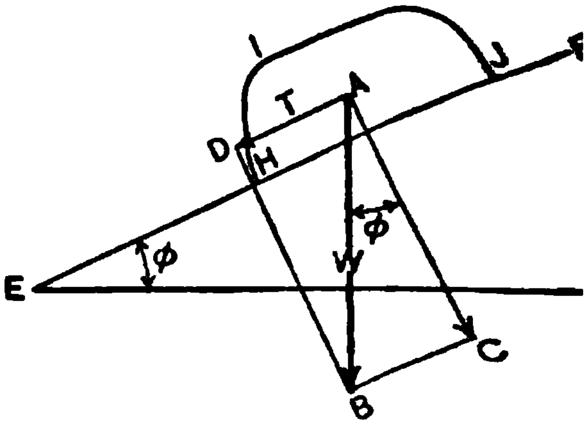

Fig. 4

Figs. 1, 2, 3 and 4. Body on Inclined Plane. Graphical Representation of F

becomes so great that the FRICTION developed between the surfaces of tl and the plane is no longer sufficient to prevent the body from slidin the plane (Fig. 1).

Assume the body HIJ resting on the plane EF. The weight, W, of th is shown graphically by the line AB, applied at its center of gravity A (

ight can be resolved into two component forces, one, AC, normal to the plane and the other, AD, parallel to it. It is the parallel or tangential hich tends to pull the body down the plane and which is resisted by the developed between the two surfaces. The friction developed between e surfaces in contact depends upon the nature of the materials of which e composed and the intensity of the forces pressing them together; and ts the tendency to slide only up to a certain point. As the angle ϕ, the inclined plane makes with the horizontal, increases, the tangential ent T, of the weight W, increases, until it becomes greater than the al resistance, and the body moves down the plane (Fig. 3). From metry,

$$T = W \sin\phi$$

$$N = W \cos\phi, \quad \text{or,} \quad T = N \tan\phi$$

e is evidently a position of the plane, intermediate between the positions in Figs. 1 and 3, in which the component force T is just balanced by the and in which the body remains at rest although just on the point of (Fig. 4). If the angle which the inclined plane makes with the hori-, at the moment when the body is just about to slide, be designated by ϕ, tion developed between the two surfaces will be equal to $N \tan\phi$, since, the angle of inclination of the plane to the horizontal is ϕ, the tangential ent of the weight just balances the friction. From the equation $T = N$ it is evident that the friction is directly proportional to N and to $\tan\phi$. is then known as the COEFFICIENT OF FRICTION and ϕ as the ANGLE OF t, or, in the case of stone surfaces, it is often known as the ANGLE OF se.

following Table I gives the average values of these constants as deter-by experiment.

Table I. Coefficients and Angles of Friction

Kind of surface	Coefficient of friction, tan ϕ	Angle of friction, ϕ
te, limestone and marble:		
dressed upon soft dressed	0.70	35° 00′
d dressed upon hard dressed	0.55	28 50
d dressed upon soft dressed	0.65	33 00
, brick or concrete:		
onry upon masonry	0.65	33 00
onry upon wood (with the grain)	0.60	31 00
onry upon wood (across the grain)	0.50	26 40
onry upon dry clay	0.50	26 40
onry upon wet or moist clay	0.33	18 20
onry upon sand	0.40	21 50
onry upon gravel	0.60	31 00
one upon steel or iron	0.40	21 50
tone upon steel or iron	0.30	16 40

discussion only the weight AB (Figs. 2, 3 and 4), of the body has been ed; but the body might be subjected to the action of other forces be-e force of gravity, in which case these other forces would be combined weight in order to find the resultant, this resultant being again resolved ngential and a normal component. Since the angle BAC is equal to the

angle *FEG* (Figs. 2, 3 and 4), given a certain normal pressure exerte
body on the plane, the amount of the tangential pressure T depends
angle *FEG*. The problem in actual practice reduces itself to so arran
conditions that no matter what the position of the plane may be, the
which the resultant W, makes with the normal N, to the plane, will not b
than the ANGLE OF FRICTION or REPOSE.

Theorem of the Middle Third. When any surface is subjected
sure from the action of any force or forces, this TOTAL PRESSURE may
sidered as a SYSTEM OF AN INFINITE NUMBER OF PARALLEL FORCES,
unequal in intensity. These forces will have a RESULTANT, whose MAG
DIRECTION and POINT OF APPLICATION can be determined, either graphi
by moments, as explained in Chapter VI. The determination of the
elements of this resultant force may at times become of the utmost im
to the engineer.

Pressure of this nature is technically known as the STRESS to which
face in question is subjected. (See Chapter I.) When the INTENSI
STRESS is not the same at different points of a surface, it is called a
STRESS, while if, on the contrary, its intensity remains the same at eve
of the surface, it is called a UNIFORM STRESS.

When a stress varies it may do so in one or two ways. It may v
FORMLY, that is to say, in a uniform manner, following some definit
variation, so that, knowing this law, its intensity may be determined
given point of the surface; or NON-UNIFORMLY, following no law.
stress varies in the former manner it is called a UNIFORMLY VARYING
This is the case most frequently met with in engineering problems.

Fig. 5. Resultant within Middle Third Fig. 6. Resultant at Middl

In dealing with ISOLATED FORCES, such as concentrated loads on a
are usually interested in determining the MAGNITUDE and POINT OF APP
of the RESULTANT of these forces. When, however, the question is one
or of an unlimited number of forces, the problem that usually prese
is one in which the resultant is known, in magnitude, direction and
application, and in which it is required to determine the DISTRIBUTIO
STRESS to which the surface is subjected. Or, in actual practice, it is
to so arrange the parts of the structure that this resultant shall have su
nitude, direction and point of application that the stress to which th
under consideration is subjected shall not exceed certain LIMITS or
determined beforehand by experience. For example, when the resul
known amount of pressure or stress acts at the CENTER OF GRAVITY o
face subjected to the stress, this stress is UNIFORMLY DISTRIBUTED
surface.

in the resultant acts at a distance of two-thirds the total width of the from one edge or boundary line of the surface, and at one-third the from the other edge, the stress is UNIFORMLY VARYING; and its IN- at the edge farthest from of application of the is ZERO and at the other MAXIMUM or twice the average When, however, the total of the stress remaining the the point of application of resultant is at a greater distance one edge than two-thirds the width of the surface, a certain of the surface adjacent to the farthest from the resultant is to a STRESS OF A CONTRARY to that distributed over

Fig. 7. Resultant beyond Middle Third

of the area; that is to say, if the stress to which the major part of the is subject is a COMPRESSIVE stress, the stress acting on the remainder of is a TENSILE stress. The stresses in a surface resulting from three positions of the resultant force may be illustrated graphically, as shown 5, 6 and 7. (See, also, Chapter XXXI, pages 1225 and 1234.)

2. Retaining-Walls

Definitions. A RETAINING-WALL is a wall built to resist the pressure of sand, or other filling or backing deposited behind it after it is built, as distinguished from a BREAST-WALL or FACE-WALL, which is a similar structure to prevent the fall of earth which is in its undisturbed, natural position, of which part has been excavated, leaving a vertical or inclined face. Fig. illustration of the two kinds of wall.

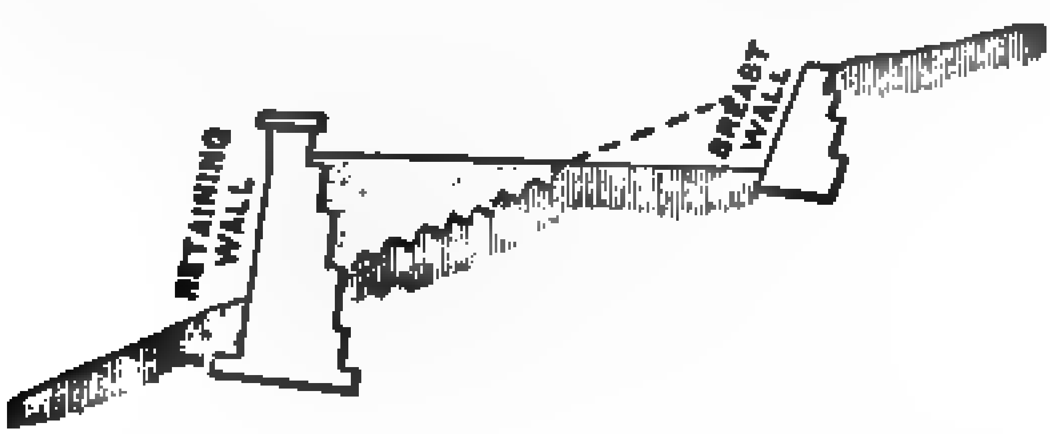

Fig. 8. Retaining-wall and Breast-wall

Theories of Retaining-Walls. A great deal has been written on the THEORY OF RETAINING-WALLS, and many theories, involving elaborate calculations for finding the CONJUGATE PRESSURES in the earth-backing behind the wall, have been developed for computing the THRUST which a bank of earth exerts against such a wall, and for determining the FORM of wall which offers the greatest resistance with the least amount of material. There are so many conditions, however, upon which the thrust exerted by the backing depends, such as the cohesion of the earth, the dryness of the material, the mode of backing up the wall, etc., that in practice it is impossible to determine the exact thrust which is exerted against a wall of a given height. It is necessary, therefore, in designing retaining-walls, to be guided by experience rather than by theory. As theories of retaining-walls are so vague and unsatisfactory, we shall not

include any in this work, but offer, rather, such suggestions, rules and
as have been established by practice and experience. A constructi
gested from empirical data, which has been found to work well in prac
determining the THRUST OF THE EARTH-BACKING and the DIMENSIONS
WALL to properly resist this thrust, is given on page 257.

In designing a retaining-wall the backing as well as the wall itself
carefully considered. THE TENDENCY OF THE BACKING TO SLIP is ver
less when the material is in a dry state than when it is saturated wit
and hence every precaution should be taken to secure good drainage.
surface-drainage, there should be openings left in the wall for the wate
may accumulate behind it to escape.

The manner in which the material is filled against the wall, also, aff
stability of the backing. If the ground is made irregular, with stepp
shown in Fig. 8, and the earth well rammed in layers inclined DOW
the wall, the pressure will be very trifling, provided that attention is
drainage. If, on the other hand, the earth is tipped in the usual ma
layers sloping DOWN TOWARDS the wall, almost the full pressure of t
will be exerted against it, and it must be made strong enough to w
such pressure.

Slopes of Repose and Angles of Repose. Cases may occur in pr
which the conditions are not such as are shown in Fig. 8, which show
limited amount of fill or new material put in behind the wall on to
original slope of the grade; cases in which, on the contrary, the wall
built on the natural surface of the ground with a view to creating an
new terrace or embankment and where all the material back of the wal

All of this material does not beat upon the wall and tend to overtu
sand or loose earth taken from an excavation and deposited on the s
the ground does not spread itself out like a liquid but piles up in a moun
PILING UP is due to the FRICTION developed between the separate pa
they slide one over the other while being dumped. This phenomenon is
in the action of any solid material broken up into separate particles; and
the SLOPE OF THE SIDES of such a mound varies with different materi
in general, the same for the same material. The angle of this slope is k
the ANGLE OF NATURAL SLOPE of the material. This angle for the mate
erally used for fill is given in the following Table II.

Table II. Slopes of Repose, Angles of Repose and Weights of L Materials

Kind of earth	Slope of repose*	Angle of repose	We lb
Sand, clean	1.5 to 1	33° 41′	
Sand and clay	1.33 to 1	36 53	
Clay, dry	1.33 to 1	36 53	
Clay, damp, plastic	2 to 1	26 34	
Gravel, clean	1.33 to 1	36 53	
Gravel and clay	1.33 to 1	36 53	
Gravel, sand and clay	1.33 to 1	36 53	
Soil	1.33 to 1	36 53	
Soft rotten rock	1.33 to 1	36 53	
Hard rotten rock	1 to 1	45 00	
Bituminous cinders	1 to 1	45 00	
Anthracite ashes	1 to 1	45 00	

* The slope is that of horizontal to vertical projection.

ssures on Retaining-Walls. Even under the conditions shown in Fig. 8, a part of the filled-in material will exert a pressure on the wall. It would atural to suppose that the part of the fill exerting pressure on the wall ill be determined by the ANGLE OF NATURAL SLOPE, all material from a al horizontal grade up to this angle being able to take care of itself, and he material above the angle needing the wall to hold it in place. Experi-t shows that this is not strictly true, for as the earth settles into place certain es of INTERNAL ELASTICITY and tendencies toward a state of EQUILIBRIUM e into play creating INTERNAL STRESSES which produce the CONJUGATE sures already referred to. The exact determination of these INTERNAL sses demands relatively complicated calculations which would be out of e in a book of this character. The construction given in the following agraphs for determining the SLOPE OF THE CLEAVAGE-PLANE, between that t of the backing which sustains itself and the triangular fill which actually s on the wall, is sufficiently accurate, however, for all practical purposes.

he Slope of the Cleavage-Plane. The following construction (Figs. 9 10), based upon empirical data, for determining first, the PRISM OF EARTH

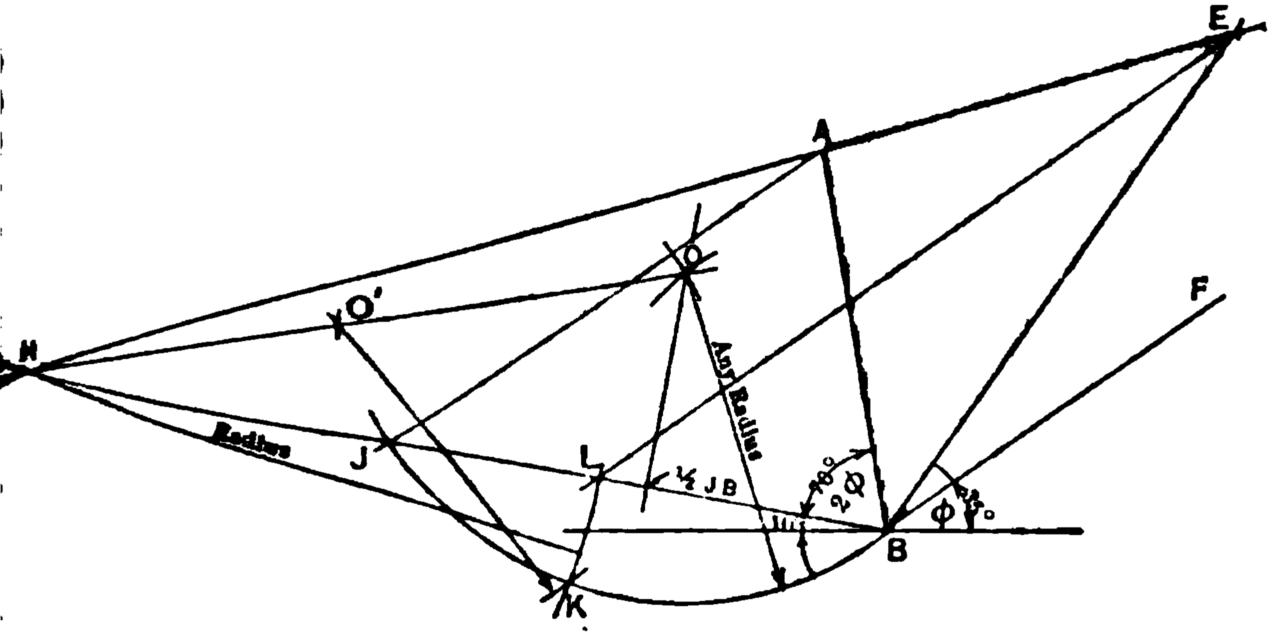

Fig. 9. Method of Determining the Prism of Earth

h exerts pressure on the back of the wall and secondly, the proper DIMEN-s for the wall, has been found to work well in practice, when certain neces-precautions are taken. These include proper DRAINAGE behind the wall, er RAMMING of the fill and efficient BRACING of the wall during its construc-.

n the calculations to determine the pressure of the earth and the weight of wall, a slice 1 ft thick is first considered. Then the area of the triangle is proportional to the volume and weight of the slice of earth causing ure on the wall, and as the area of the cross-section of the wall is propor-l to the volume and weight of the slice of the wall itself.

o determine the PRISM OF EARTH which exerts pressure against the back of wall, decide first upon the BATTER to be given to the back of the wall. In case it made 80° with the horizontal, an angle slightly greater than that ed by Trautwine. Draw *BH* (Fig. 9), making an angle *ABH*, equal to with the back of the wall; continue this line until it meets at *H* the slope e surface of the earth back of the wall, prolonged. From *A*, the top of the draw *AJ* parallel to *BF* the natural slope of the fill. This has been taken , as a fair average value. Erect a perpendicular from the middle of *JB*. With any point, *O*, as a center, on this perpendicular, describe an arc passing

through J and B. Draw HO and bisect it, and with O' as a center and O a radius, describe the arc cutting the arc JKB at K. Again, with a radius and with H as center, describe the arc KL, and finally, from L, draw LE pa to JA. The intersection of this line with the surface of the ground locate

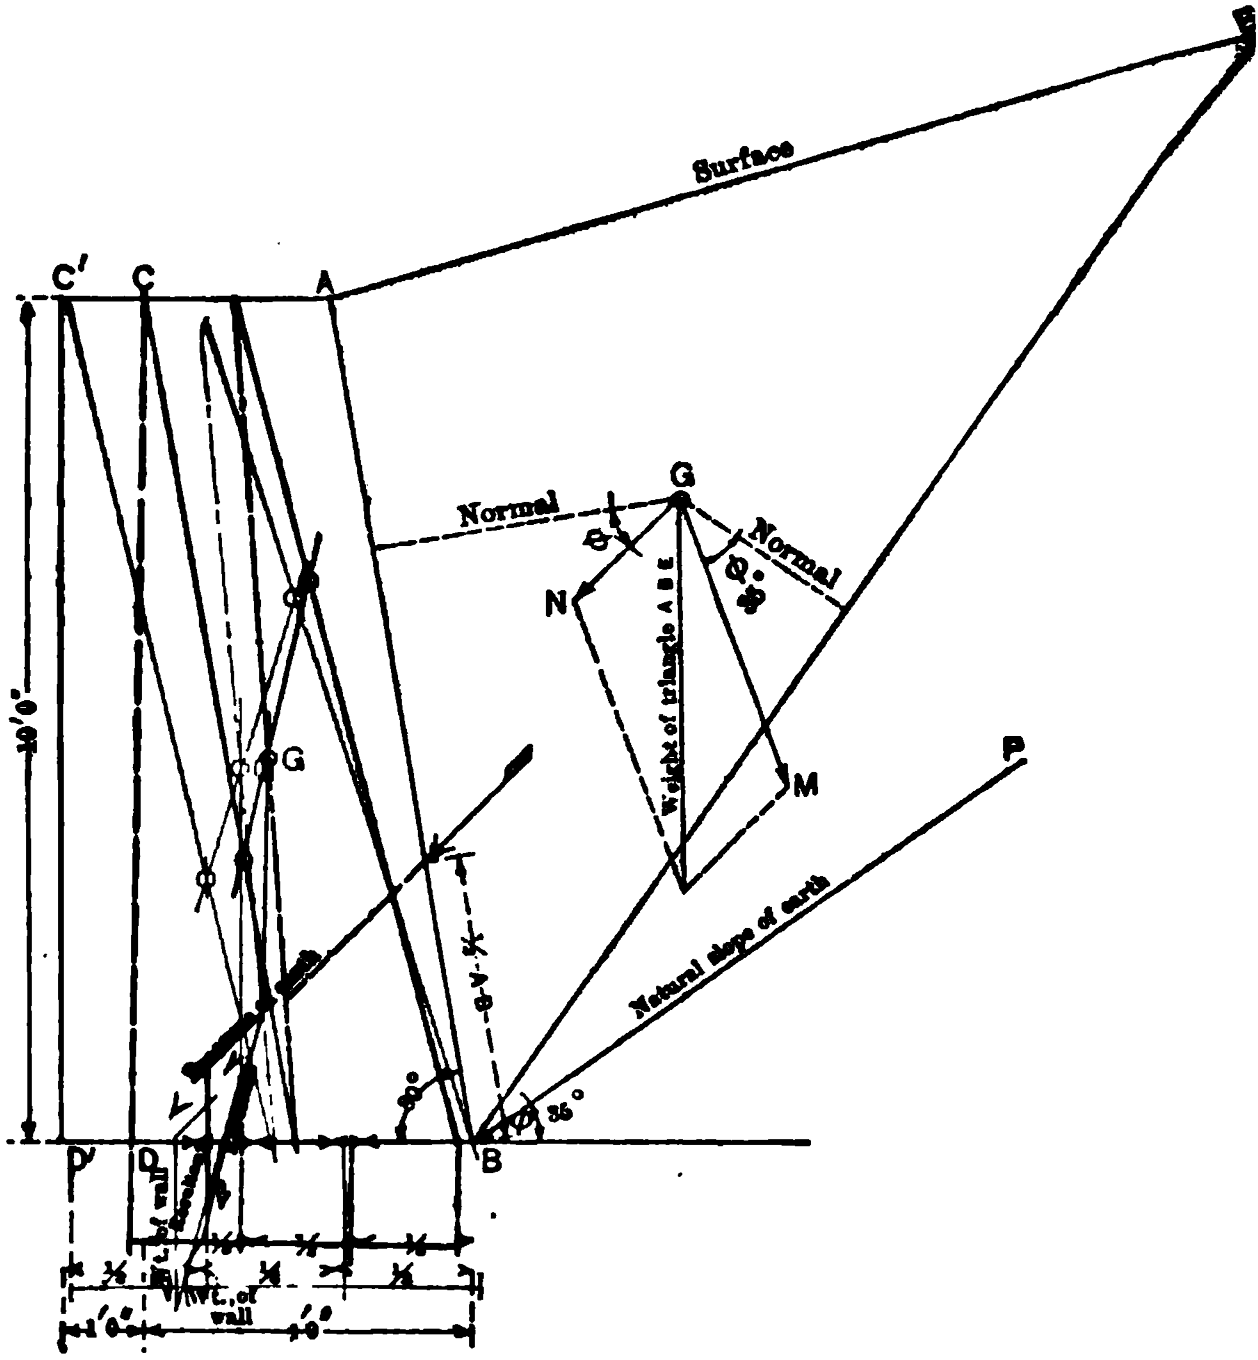

Fig. 10. Method of Determining Dimensions of Retaining-wall

point E. The line EB is the line of the CLEAVAGE-PLANE which separat part of the backing which bears against the wall from the part which exe lateral pressure.

Having found the DIMENSIONS OF THE VOLUME OF EARTH, the thrust of must be resisted by the wall, the next step is to determine what the DIMEN OF THE WALL should be to properly resist this thrust. Usually one or two are necessary before the proper solution of the problem is found. In th ample given, a preliminary trial was made with a thickness at the base o This construction is shown with the green lines (Fig. 10).

After drawing the triangle representing the base of the PRISM OF EARTH its center of gravity, G (Chap. VI). From this point draw two normals, the back of the wall and the other to the line of the CLEAVAGE-PLANE. the two lines, GM and GN, making angles ϕ with these normals. Lay o tically from the center of gravity, at any convenient scale of so many

to the linear inch, the area of the triangle of the base of the prism, the as already explained, being proportional to the volume of the prism and ight. Resolve this weight-line along the two lines GM and GN (Chap. This will give the MAGNITUDE and DIRECTION of the THRUST or pressure earth against the wall. Apply this pressure at a point on the back of the one-third of the distance from the bottom, as shown by the arrow. This the force which may tend to OVERTURN the wall and which tends to make it along the base. (See Fig. 6.)

To resist these OVERTURNING and SLIDING-TENDENCIES, the weight of the wall bined with the pressure of the earth behind it should produce a resultant satisfies the following conditions. First, its MAGNITUDE should not great enough to cause a unit pressure on the foundation-bed greater than safely bear; secondly, it should pass within the MIDDLE THIRD of the base the stress over the entire area of the base will be a COMPRESSIVE stress; thirdly, it should make an angle with a normal to the plane of the founda-bed not greater than the ANGLE OF FRICTION between the stone, brickwork, crete, or other masonry of the footings and the sand, clay, or rock of the foun-bed.

In order to determine these conditions, the CENTER OF GRAVITY of the cross-tion of the wall must be determined and a vertical line drawn through this until it intersects the line of the EARTH-THRUST produced. It is at this section of the LINES OF ACTION of the two forces that their RESULTANT To find the CENTER OF GRAVITY of the cross-section of the wall, the method dividing the trapezoid into two triangles has been followed, the center of ity of each triangle being found and these two points being joined by a line. intersection of this line with the median line drawn between the base and top of the wall is the center of gravity of the trapezoid. In this example, convenience, the scale used for the composition of the forces of the pressure the earth and the weight of the wall is one-half the scale used for the ition of the forces representing the weight of the earth-prism.

In the first trial, shown by the green lines, the first and third conditions neces-y to insure stability are fulfilled; but the second is not, the resultant pass-outside the MIDDLE THIRD of the base. This indicates, theoretically, a TENSILE stress or a tendency for the joints at the back of the wall to open. other trial, therefore, is shown with the red lines, the thickness of the wall increased as shown by the rectangle $CC'D'D$. In this second trial the OF THE WALL is necessarily increased while the EARTH-THRUST remains same. As in this case the resultant passes within the middle third, it is cluded that a wall of these dimensions, 5 ft base by 10 ft height and with batter, will be safe and will properly resist the thrust of the earth-ling.

ails of Construction. Retaining-walls are generally built with a BATTER-that is, a SLOPING face, as walls of this form are the strongest for a given of material; and if the courses are INCLINED DOWN TOWARDS THE BACK, the ncy to slide on each other will be resisted, and it will not be necessary to upon the adhesion of the mortar. The importance of making the resist-independent of the adhesion of the mortar is obviously very great, as it otherwise be necessary to delay the backing up of the wall until the mortar thoroughly set, which might require several months.

brickwork it is advisable to let every third or fourth course below the frost-project an inch or two. This increases the friction of the earth against and causes the resultant of the forces acting behind the wall to become nearly vertical, and to fall farther within the base, increasing the stability

It also conduces to strength to make the courses of varying heights throu the thickness of the wall, and to have some of the stones, especially thos the back, sufficiently high to extend through two or three courses. By means the whole masonry becomes more effectually interlocked or b together as one mass and is less liable to bulge. The courses of masonr often laid with their beds SLOPING IN, as in Fig. 15, to overcome the ten of the courses to slide on each other.

Where the ground freezes to a great depth, the back of the wall shou SLOPED FORWARD for three or four feet below its top surface, as at OC (Fig

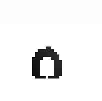

Fig. 11. Retaining-wall for Deep-freezing Earth

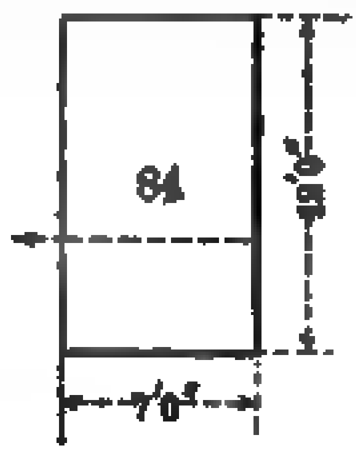

Fig. 12. Retaining-wall with Rectangular Cross-section

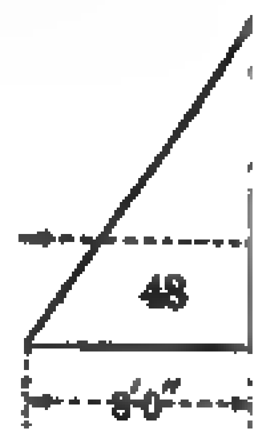

Fig. 13. Ret wall with Tri Cross-section

and this slope should be quite smooth, so as to lessen the hold of the fro prevent displacement.

Figs. 12, 13, 14 and 15 show the approximate RELATIVE VERTICAL SECT AREAS of walls of different shapes that would be required to resist the pr of a bank of earth 12 ft high. The first three examples are calculated to the maximum thrust of wet earth, while the last shows the modified form usually adopted in practice.

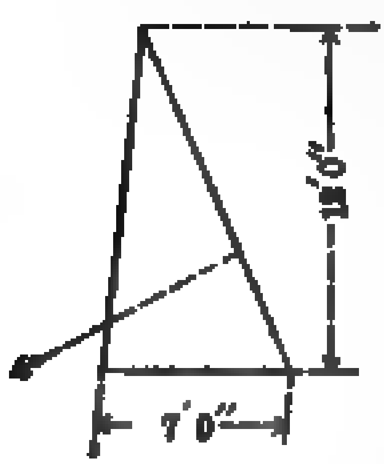

Fig. 14. Retaining-wall with Triangular Cross-section

Notes on the Thickness of Retaining-Walls. As has been stated, about the only practical rules for retaining-walls are the empirical rules based upon experience and tests. Trautwine* gives the following Table III for the thickness at the base of vertical retaining-walls with a sand backing deposited in the usual manner. The first column contains the vertical height CD (Fig. 16) of the earth as compared with the vertical height of the

Fig. 15. Ret wall with S Back

wall, AB. The latter is assumed to be 1, so that the table begins w backing of the same height as the wall. These vertical walls may be ba to any extent not exceeding 1½ in to 1 ft, or 1 in 8, without affecting stability and without increasing the base.

If the wall is built as in Fig. 17, with the ground practically level wi top, the top of the wall should be not less than 18 in thick, and the thick at a, a, etc., just above each step, should be from one-third to two-fifths

* The Civil Engineer's Pocket-Book, John C. Trautwine.

(Chapter IX) and the necessary DIMENSIONS and REINFORCEMENT to
vided decided by the rules given in Chapter XXIV.

3. Breast-Walls

Breast-Walls. Where the ground to be supported is firm, and the st
horizontal, the office of a BREAST-WALL (Fig 8) is more to protect than to
the earth. It should be borne in mind that a trifling force skilfully applie
broken ground will keep in its place a mass of material, which, if once al
move, would crush a heavy wall. Great care, therefore, should be take

the newly opened ground to the influence of air and water longer than is for sound work, and to avoid leaving the smallest space for motion the back of the wall and the ground. The strength of a breast-wall must rtionately increased when the strata to be supported incline down

Fig. 20. Reinforced-concrete Retaining-wall with Counterforts and Apron

the wall; where they incline down from it, the wall need be little more thin facing to protect the ground from disintegration. The preserva- f the natural drainage is one of the most important points to be d to in the erection of breast-walls, as upon this their stability in a easure depends. No rule can be given for the best way to do this; it tter for attentive consideration in each particular case.

4. Vault-Walls

-Walls. In large cities it is customary to utilize the space under the t for storage or other purposes. This necessitates a wall at the curb- hold back the earth and the street-pressures and also the weight of the . Where practicable the space should be divided by partition-walls y 10 ft, and when this is done the outer wall may be advantageously —d bricks in the form of arches, as shown in Fig. 21. The thickness

of the arch should be at least 16 in for a depth of 9 ft and the rise (arch from one-eighth to one-sixth of the span. If partitions are not p cable, each sidewalk-beam be supported by a heavy I column, with either flat o mental arches between, of brick or concrete. Fig. shows a detail of the outer of the vault under the sic around the Singer building York City. These walls (of a core formed by tw brick arches with vertical built between the flang 8-in vertical steel I spaced about 5 ft apa bedded at the bottom in crete footing. Their to joined by 6-in horizontal I beams and braced laterally by the sidewalk- 5 ft apart. The arches themselves are segmental, with a rise of abou

CHAPTER V

[ST]RENGTH OF BRICKS, STONE, MASS-CONCRETE AND MASONRY

By
THOMAS NOLAN
[PROF]ESSOR OF ARCHITECTURAL CONSTRUCTION, UNIVERSITY OF PENNSYLVANIA

1. Crushing Strength of Stonework, Brickwork, Bricks, etc.

[Stre]sses in Masonry. By the term STRENGTH OF MASONRY is generally [mean]t its resistance to a direct COMPRESSIVE force or load, and this is the only [kind of] stress to which masonry should be subjected. Stone lintels and footings [may] be subjected to a TRANSVERSE or BENDING STRESS, but they can hardly be [inclu]ded in the term masonry, as they consist of single pieces. There are also [tenden]cies to bend and to split apart in brick walls and piers, as they are usually [h]i[gh] in proportion to their lateral dimensions, but the stresses thus developed [canno]t be accurately determined and should be avoided as much as possible. [It is] impossible to fix values for the strength of brickwork or stonework with [anyth]ing like the exactness possible for wooden or steel members, for the reason [that] there is not only a great variation in the strength of different kinds of [brick] and stone, even when taken from the same kiln or quarry, but the strength [of wa]lls and piers is also greatly affected by the kind and quality of the mortar [used], the way in which the work is built and bonded, and the amount of moisture [in th]e materials when they are laid. All that can be done, therefore, is to give [value]s which will be safe for the different kinds of masonry built in the usual [mann]er.

[Wor]king Compressive Strength of Masonry. The building laws of most [of th]e larger cities of this country specify the maximum loads per square foot [allow]ed to be placed upon different kinds of masonry, and these laws must govern [arch]itects in such cities. When there is no restriction of this kind, Table I [give]s a pretty good idea of the maximum loads which it is safe to put upon the [differ]ent kinds of work mentioned. Table II gives the maximum safe loads [specif]ied in the building laws of several cities, and the remaining tables of the [chapt]er give records of numerous tests made to determine the ultimate com[press]ive strengths of various kinds of bricks, building stones, mortars and con[crete]s, and are of value in determining the safe loads for special cases. In [deter]mining the safe compressive resistance of masonry from tests on the ulti[mate] compressive strength of work of the same kind, a factor of safety of at [least] 10 should be allowed for piers and 20 for arches.

Table I. Safe Working Loads for Masonry

BRICKWORK IN WALLS OR PIERS

	Tons per square foot Eastern	Tons per square foot Western
[Common b]ricks in lime mortar	7	5

Brick Piers. As a rule brickwork is subject to its full safe resistanc when used in piers, and in small sections of walls, under bearing-plates. latter case but a few courses receive the full load, and hence a greate stress may be allowed than for piers. Values for computing the area of be plates are given in Chapter XIII. Aside from the quality of the wor materials the two elements which most influence the strength of brick are the ratio of height to least lateral dimension and the method of be When the height of a brick pier exceeds six times its least lateral dimensi load per square foot should be reduced from the values given in Table I.

Formulas for the Safe Strength of Brick Piers exceeding six dia in height. From the records of numerous tests on the strength of brick from some formulas published * by Ira O. Baker, and also from personal vation, Mr. Kidder deduced the following formulas for the maximum w loads for first-class brickwork in piers whose height exceeds six times th lateral dimension.

For piers laid with rich lime mortar:

$$\text{Safe load per square inch} = 110 - 5\ H/D$$

For piers laid with 1 : 2 natural-cement mortar:

$$\text{Safe load per square inch} = 140 - 5\tfrac{1}{2} H/D$$

For piers laid with 1 : 3 Portland-cement mortar:

$$\text{Safe load per square inch} = 200 - 6\ H/D$$

H representing the height in feet, and D the least lateral dimension in fe

For a pier 20 ft high and 2 ft square these formulas will reduce the s to 4.3 tons per sq ft for lime mortar, 6.1 tons for natural-cement mor 10 tons for Portland-cement mortar. No pier over 8 ft high should be l 12 by 12 in in cross-section and when from 6 to 8 ft high piers should be 8 by 12 in in cross-section.

The following is the Chicago law (1914): "Isolated piers of concret or masonry shall not be higher than six times their smallest dimension the above unit stresses ‡ are reduced according to the following formula

$$P = C\,(1.25 - H/20\,D)$$

in which P is the reduced allowed unit load, C the unit stress above to, H the height of the pier in feet and D the least dimension of the pie No pier shall exceed in height twelve times the least dimension. Th of the pier shall be added to other loads in computing the load on the

Brick piers intended to carry more than 50% of the safe loads give should not be built in freezing weather nor with dry bricks. Lime should not be used for building piers that are to receive their full loa three months.

Effect of Bond on the Strength of Brickwork. Brick piers, l the point of destruction, always fail by the splitting and bulging ou

* In the Brickbuilder, April, 1898.

† For piers faced with pressed bricks, laid with joints ¼ in or less in thick backed with common bricks in lime mortar, only the dimensions of the backing considered in figuring their strength. If the backing is laid in cement morta face-bricks are well tied to the backing, the full section of the pier may be consid piers veneered with stone or terra-cotta, 4 in thick, only the strength of the back be considered.

‡ These are in general the "safe working pressures" for brickwork previously as recommended by the Chicago architects and engineers in 1908.

...selves, and not by direct crushing of the bricks or mortar, showing ...s are weakest in their bond and in the tensile or transverse strengths of ...ks. It is very important, therefore, to have the brickwork well bonded, ...l joints filled with mortar or grouted. The strength of a brick pier in... to carry an extreme load would probably be increased by bonding fre... with hoop-iron in addition to the regular brick-bond.*

...d-Stones in Brick Piers. Many competent architects and builders ...r that the strength of a brick pier is increased by inserting bond-stones, ...5 to 8 in in thickness and the full size of the pier in cross-section, every 3 or ... height.

...example, the Building Laws for the City of New York (1916) require ...stones every 30 in in height, and at least 4 in in thickness, to be built into ...piers which contain less than 9 superficial feet of section, and which sup... beam, girder, arch, or column on which a wall rests, or lintel spanning ...ning over 10 ft and supporting a wall. The New York laws allow per...d steel or cast-iron plates of the full cross-section of the pier to be used ...d of the bond-stones. On the other hand, there are many first-class ...s who consider that bond-stones in a brick pier do more harm than good, ...he author is of the opinion that this is generally the case. The Boston ...ng Laws do not require intermediate bond-stones. If bond-stones are ..., they should be bedded so as to bear rather more heavily on the inner ...n of the pier than on the outer 4 in, for unless this is done the outer shell ...the most of the load, and will be likely to bulge away from the core. A ...hich supports a girder or column should have a cap-stone or iron plate of ...ent strength to distribute the pressure over the cross-section of the pier.

...lls Faced with Stone, Terra-Cotta, or Cement Blocks. Brick walls ... with blocks or ashlar of any material should always have the backing laid ...ment mortar or in cement-and-lime mortar, unless the backing is very ..., that is, 30 in or more. The aggregate thickness of the mortar joints in ...acking is so much greater than in the facing, that any shrinkage or com...ion of the mortar tends to throw undue weight on the facing and to sepa...t from the backing. Veneering generally should be tied to the backing ...t every 18 in in height. Stone courses, up to about 36 in in height, ... have anchors in the bed-joints only. Anchors are placed in the side ... also, when the height of the courses is more than 36 in. The Building ...ances of several large cities require that all bearing walls faced with ... laid in running bond, and all walls faced with stone ashlar less than 8 in ... shall be of such thickness as to make the wall independent of the facing ...n to that required for unfaced walls. Ashlar 8 in thick and bonded into ...cking may be counted as part of the thickness of the wall.

...uting.† It is contended by persons having large experience in building ...asonry carefully grouted, when the temperature is not lower than 40° F., ...e the most efficient result. Many of the largest buildings in New York ...ave grouted walls. The Mersey docks and warehouses at Liverpool, ...d, one of the greatest pieces of masonry in the world, were grouted ...hout. There are many engineers and others who do not believe in ...g, claiming that the materials tend to separate and form layers.

...hing Height of Bricks and Stone. If we assume that the weight of ...ork is 120 lb per cu ft, and that it would commence to crush under 700 lb

* ...e manner in which brick piers fail is excellently shown by illustrations on page 79 ...rickbuilder for May, 1896.

† ...e American Architect, July 21, 1887, page 11.

per sq in, then a wall of uniform thickness would have to be 840 ft high the bottom courses would commence to crush from the weight of the bric above. Average sandstones, at 145 lb per cu ft, would require a column 5 high to crush the bottom stones, and an average granite, at 165 lb per would require a column 10 470 ft high. The Merchants' shot-tower at more is 246 ft high, and its base sustains a pressure of 6½ tons per sq ft, tl being long tons of 2 240 lb. The base of the granite pier of Saltash Brid Brunel), of solid masonry to the height of 96 ft, and supporting the ends iron spans of 455 ft each, sustains 9½ tons per sq ft.

Stone Piers. Piers of good strong building stone laid in courses t cross-sections of the piers, with the top and bottom courses bedded tr even, may be built to support very heavy loads. The height of such however, should not exceed ten times the least lateral dimension, and w exceeds eight times the thickness, the load should be reduced. The should not exceed ⅜ in in thickness and should be spread with 1 : 2 Po cement mortar, kept back 1 in from the face of the pier to prevent spal the edges. A test of the strength of a limestone pier 12 in square is de under Marbles and Limestones, in this chapter. Rubble-work should used for piers whose height exceeds five times the least dimension, or in the latter is less than 20 in.

Records of Tests on the Crushing Resistance of Bricks. Tal gives the results of some tests on bricks, made under the direction of Mr. in behalf of the Massachusetts Charitable Mechanics' Association.

specimens were tested in the government testing-machine at Watertown, and great care was exercised to make the tests as perfect as possible. parallel plates between which the bricks are crushed are fixed in one position it is necessary that each specimen tested should have perfectly parallel The bricks which were tested were rubbed on a revolving bed until the bottom faces were perfectly true and parallel. The preparation of the in this way required a great deal of time and expense; and it was so difficult some of the harder bricks that they had to be broken and only one-half brick prepared at a time.

Philadelphia bricks used in these tests were obtained from a Boston and were fair samples of what is known in Boston as Philadelphia Face- They were very soft bricks.

Cambridge bricks were the common bricks, such as are made around They are about the same as the Eastern bricks.

Boston Terra-Cotta Company's bricks were manufactured of a rather and were such as are often used for face-bricks.

New England pressed bricks were hydraulic-pressed bricks, and were as hard as iron.

tests made on the same machine by the United States Government in the average strength of three (M. W. Sands) Cambridge, Mass., face- was 13 925 lb, and of his common bricks, 18 337 lb per sq in, one brick the enormous strength of 22 351 lb per sq in. This was a very hard- brick. Three bricks of the Bay State (Mass.) manufacture showed an strength of 11 400 lb per sq in. The New England bricks are among and strongest in the country, those in many parts of the West not one-fourth the strength given above; so that in heavy buildings, where strength of the bricks to be used is not known by actual tests, it is advisable the bricks tested. Ira O. Baker reported some tests on Illinois bricks, on the 100 000-pound testing-machine at the University of Illinois in 1889, which give for the crushing strength of soft bricks, 674 lb per sq in, average of three face-bricks, 3 070 lb per sq in, and for four paving- 9 775 lb per sq in. In nearly all makes of bricks it will be found that the bricks are not as strong as the common bricks.

of the Strength of Brick Piers Laid with Various Mortars.* tests were made for the purpose of testing the strength of brick piers with different cement mortars, as compared with those laid up with mortar. The bricks used in the piers were procured at M. W. Sands's Cambridge, Mass., and were good ordinary bricks. They were from lot as the samples of common bricks described above. The piers by 12 in in cross-section, and nine courses, or about 22½ in high, except- first, which was but eight courses high. They were built Nov. 29, 1881, of the storehouses at the United States Arsenal in Watertown, Mass. In have the two ends of the piers perfectly parallel surfaces, a coat of pure cement, about ½ in thick, was put on the top of each pier and the foot in the same cement. On March 3, 1882, three months and five the tops of the piers were dressed to plane surfaces at right-angles sides of the piers. On attempting to dress the lower ends of the piers, grout peeled off, and it was necessary to remove it entirely and put of cement similar to that on the tops of the piers. This was allowed for one month and sixteen days, when the piers were tested. At that piers were four months and twenty-six days old. As the piers were cold weather, the bricks were not wet. They were built by a skilled

* Made under the direction of F. E. Kidder.

bricklayer and the mortars were mixed under his superintendence. Th
were made with the government testing-machine at the Arsenal. The
ing table is arranged so as to show the result of these tests, and to afford
means of comparison of the strength of brickwork with different mortars
piers generally failed by cracking longitudinally, and some of the bricl
crushed. The Portland cement used in these tests was made by Brooks
bridge & Company, of England. Roman cement is a European natural
usually, although not always, containing a low percentage of magne
sets rapidly, has about one-third the strength of true Portland cement
much weakened by the addition of sand.

Table IV. Tests of Piers of Common Bricks Laid in Different Mo

Piers 8 by 12 in in section, built of common bricks.	Ultimate strength of pier, lb	Pressure per sq in under which pier commenced to crack, lb	Ult str lb

10 to 10½ ft. The lateral dimensions were 12½ by 12½ in. Two g of bricks were used, an excellent class of building bricks and a soft grade se as representative of inferior bricks. Different qualities of mortar and dif grades of workmanship were employed. Compression-tests of single gave these average results. For hard, shale building bricks, bedded in u crushing strength, flatwise, 10 700 lb per sq in; modulus of rupture, edg 6-in span, 1 670 lb per sq in. For soft or underburned clay bricks, cr strength, flatwise, 3 900 lb per sq in; modulus of rupture, 480 lb per The Macgregor tests showed that maximum strength with minimum e for brickwork is obtained with mortar made of ½ cu ft of Portland c ½ cu ft of hydrated lime and 3 cu ft of sand, or a 1 : 1 : 6 mixture.

Tensional Strength of Brickwork. See Chapter II, page 179.

2. Strength of Terra-Cotta and Terra-Cotta Piers

General Properties of Terra-Cotta. The lightness of terra-cotta, com with its great compressive strength, together with its relatively high res to the effects of heat and fire, renders it an especially valuable building ma Terra-cotta for building purposes, whether plain or ornamental, is ge made of hollow blocks formed with webs to give extra strength and ke work true while drying. This is necessary because good, well-burned, cotta cannot safely be made more than about 1½ in thick, whereas, w quired to bond with brickwork, it must be at least 4 in thick. When the cotta work does not project beyond the face of the wall these hollow spa generally filled with concrete or brickwork. For additional data regard fire-resisting properties and strength of ornamental and structural terr see Chapter XXIII, pages 814, 815, and 816.

Crushing Strength of Terra-Cotta Blocks. Some exhaustive expe made by the Royal Institute of British Architects give the following re the crushing strengths of terra-cotta blocks:

	Crushin per
Solid block of terra-cotta	523
Hollow block of terra-cotta, unfilled	186
Hollow block of terra-cotta, lightly made and unfilled	80

Tests of terra-cotta manufactured by a New York Company, whi made at the Stevens Institute of Technology in April, 1888 gave these

	Crushing weight per cu in		Crushin per
Terra-cotta block, 2-in square, red	6 840 lb	or	492
Terra-cotta block, 2-in square, buff	6 236 lb	or	449
Terra-cotta block, 2-in square, gray	5 126 lb	or	369

In tests for the New York Building Department, made at Columbia Un dense terra-cotta blocks developed a net crushing strength of 4 721 lb p or 340 tons per sq ft, and semiporous, 2 168 lb per sq in or 156 tons p these results being in each case the averages of a series of tests. (See p

From these results, the writer would place the safe working strength cotta blocks in the wall at 5 tons per sq ft when unfilled, and 10 tons when filled solid with brickwork or concrete.

...s of Terra-Cotta Piers. Tests * of terra-cotta block piers were made at the same time (January, 1907, and January, 1908) that the brick piers ...ed to in Table VII were made. The tests were made on terra-cotta piers, ...ngths of which varied from 9 ft 9 in to 12 ft 7¾ in. The lateral dimensions ...d from 8½ by 8½ in to 17½ by 17½ in. "The piers were built and tested ... lots, an interval of about one year separating the times of making the ... The two lots of piers were built of blocks which came in different ship... The cement used was the same brand in both years, although the lots

...e different. The terra-cotta block piers were generally made in sets of two. ... set was constructed and loaded similarly. Three of the piers were laid up ...ly (poorly laid); the remainder were built with the usual care given to ... work. The load was applied to the piers in different ways, although gen...ied continuously to failure." Some piers were loaded eccentrically ...nd one was loaded both concentrically and eccentrically, but the ...ccentric load was not sufficient to cause failure.

...tin No. 27, University of Illinois Engineering Experiment Station, Sept. 19...

Comparison of Results of Tests of Brick and Terra-Cotta Piers the tests summarized in Tables VII and VIII, "both the brick piers an terra-cotta block piers gave high strengths in all cases where strong morta care in building were used. The effect of the strength of the mortar was a ent in the carrying capacity developed in the piers, smaller loads being cated for piers built with 1 : 5 Portland-cement mortar than for those with Portland-cement mortar, and still smaller loads for those with 1 : 2 lime m The effect of the quality of the bricks is shown in the piers made with in bricks, these piers carrying only 31% as much as piers built with the l grade of bricks. In the case of the terra-cotta piers, the blocks which culled out as somewhat inferior gave a pier-strength which was perhaps less than the piers built with superior blocks. The effect of the attem represent hurried or careless workmanship in two brick piers and in three cotta block piers was a loss in strength of about 15% and 25% respective

"In the well-built brick piers, concentrically loaded, the ratio of streng pier to compressive strength of individual brick ranged from 31 to 37% in the underburned clay-brick pier the ratio was 27%. In the terra- block piers, concentrically loaded, the ratio of strength of pier to that of in ual block was 74% (an incompleted test) and 83, 85 and 89% for the o The higher ratio found for the terra-cotta block piers than for brick piers gests that the ability of individual pieces to resist transverse forces is a ment in the strength of the completed pier; and this suggestion may ha important bearing on the advantageous size of the component blocks may be used in a compression-piece where great strength is required.

"The strength of the pier is greater than that of the mortar-cubes in brick and terra-cotta block piers, except the soft-brick piers, which had b of low compressive strength. Both the strength of the individual bric blocks and the strength of the mortar affect the resistance of the pier, an relative effect of the two depends upon the character of the materials. evident, however, that the better the individual piece the more important to have a mortar of high resisting strength.

"The results obtained in applying the loads eccentrically were found to very well with those obtained from ordinary analysis.

"The quality of workmanship in laying up such columns has an impo bearing upon the resisting strength. The work of building piers, howev not difficult and requires only ordinary care. Full joints and an even be are important, and the ordinary workman ought to be able to construct of great strength. In the tests made on piers intended to represent po careless workmanship, the decrease in strength was not as much as anticip However, it must be understood that careful and trustworthy work is ess and that a few poor joints will materially reduce the strength of the stru Wherever good material and good workmanship are insured the streng masonry of this kind may be utilized with advantage."

Strength of Terra-Cotta Brackets or Consoles. A cornice-mod made by the Northwestern Terra-Cotta Company, 11½ in high at the wall 8 in wide on the face, and with a projection of 2 ft, was built into a wall an upper surface loaded with 2 tons of pig iron without any effect upon the modi Another bracket, 5½ in high, 6 in wide and with a 14-in projection, ma the East, broke at the wall-line under 2 650 lb, while a duplicate of it sust 2 400 lb for one month without breaking.*

The Weight of Terra-Cotta. The weight of terra-cotta in solid bloc 120 or 122 lb per cu ft. When made in hollow blocks 1½ in thick the w

* See The Brickbuilder, Vol. 7, page 142.

is from 65 to 85 lb per cu ft, the smaller pieces weighing the most. For 12 by 18 in or larger on the face, 70 lb per cu ft will probably be a fair ge. The tables in the manufacturers' catalogues give the various bearing-weights per square foot, thicknesses of parts, sizes of blocks, etc., for por- and semiporous blocks for all purposes.

2. Crushing Strength of Building Stones

(1) Sandstones

ngmeadow, Mass., Stone.* Reddish-brown sandstone, two blocks about 4 in in cross-section and 8 in in height.

ck No. 1 commenced to crack at 10 333 lb per sq in, and flew from the ne in fragments at 13 596 lb per sq in.

ck No. 2 commenced to crack at 3 012 lb per sq in and failed completely 121 lb per sq in.

dstone from Norcross Brothers' Quarries, East Longmeadow, Mass., Saulsbury Stone.* Block No. 1, 4 by 4 by 8 in high, commenced to crack 50 lb and failed at 8 812 lb per sq in.

ck No. 2, 4 by 4 by 8 in high, commenced to crack at 6 500 lb and failed 92 lb per sq in.

d Saulsbury Stone.* Block No. 1, 4 by 4 by 8 in high (about), commenced ck at 12 716 lb and failed at 13 520 lb per sq in.

ck No. 2, same size as No. 1, commenced to crack at 13 953 lb and failed 650 lb per sq in.

ite Stone.* Block No. 1, 6 by 6 by 6 in, commenced to crack at 12 590 lb failed at 12 619 lb per sq in.

ck No. 2, same size as No. 1, commenced to crack at 12 185 lb and failed 874 lb per sq in.

wn Stone from the Shaler & Hall Quarry Company, Portland, Conn.† sults of the tests are as follows:

Table IX. Crushing Strength of Brown Sandstone

Dimensions			Sectional area	First crack	Ultimate strength	Classification
[illegible] in	Compressed, surface in		sq in	lb	lb per sq in	
[illegible]	2.50	2.45	6.13	84 800	13 980	1st quality

wn Stone from the Middlesex Quarry Company, Portland, Conn.‡ Four cubical blocks, about 1½ in square. Pressure per square inch at time of : No. 1, 10 928 lb; No. 2, 10 322 lb; No. 3, 8 252 lb and No. 4, 6 322 lb.

se tests were made with the United States testing-machines at Watertown l, Mass.

m tests made by Colt's Patent Fire-arms Manufacturing Company.

se tests were made with the United States testing-machines at Watertown l, Mass.

Red Sandstone * from Greenlee & Son's Quarries at Manitou, Col. specimen failed at 11 000 lb per sq in; weight, 140 lb per cu ft.

Light-Red Laminated Sandstone,† from St. Vrain Cañon, Col., a very stone, excellent for walks and foundations. Crushing strength on bed, 1 lb per sq in; weight, 150 lb per cu ft.

Gray Sandstone † (free-working) from Trinidad, Col. Crushing str 10 000 lb per sq in; weight, 145 lb per cu ft.

Gray Sandstone † from Fort Collins, Col. (laminated and similar in q to the St. Vrain stone). Crushing strength on bed, 11 700 lb per sq in; w 140 lb per cu ft. One ton of this stone measures just a perch in the wall.

(2) Granite

Red Granite † from Platte Cañon, Col. Crushing strength per square 14 600 lb; weight per cubic foot, 164 lb.

(3) Lava Stones

Lava Stone from the Kerr Quarries, near Salida, Col. Four cubical bl The results of the tests are as follows:

Table X. Crushing Strength of Lava Stone

Dimensions			Sectional area	First crack	Ultimate streng	
Height in	Compressed surface in		sq in	lb	lb	lb 1 sq
4.00	4.00	4.00	16.00	165 900	165 000	10
4.00	4.00	4.00	16.00	174 100	174 100	10
2.00	2.00	1.99	3.98	36 400	37 100	9
1.99	1.99	1.99	3.96	38 200	38 200	9

Lava Stone,‡ Curry's Quarry, Douglas County, Col. Crushing str 10 675 lb per sq in; weight, 119 lb per cu ft. Experience has shown th stone is not suitable for piers, or where any great strength is required cracks very easily.

(4) Marble and Limestone

White marble quarried at Sutherland Falls, Vt. Two cubical blocks 6 in square.§

Block No. 1 commenced to crack at 9 750 lb per sq in and failed sudde 11 250 lb per sq in.

Block No. 2 did not crack until it suddenly gave way at 10 243 lb per

Test of a Limestone Pier. A pier of Lemont limestone, 1 sq ft in cross-s and 9 ft in height, composed of seven stones with bearing surfaces plane fectly true and parallel to the natural bed and the joints washed with grout of the best English Portland cement, was tested at the Watertown A for William Sooy Smith, and only commenced to crack when the full of the machine, 400 tons, was exerted.

* These tests were made with the United States testing-machines at Wat Arsenal, Mass.

† From tests made for the Board of Capitol Managers of Colorado by State E E. S. Nettleton, in 1885, on 2-in cubes.

‡ From tests made by the Denver Society of Civil Engineers, in 1884, also cubes.

§ Tested at the United States Arsenal, Watertown, Mass.

(5) Bricks and Various Stones

Table XI gives the crushing strength of various kinds of bricks and building stones, the pressure being normal to the plane of the bed.

† This stone should not be set on edge.

(6) Additional Data on the Strength of Building Stones

Average Data for Building Stones of Good Quality. The following a relative values* are given by R. P. Miller.† SANDSTONE: weight, 150 cu ft; specific gravity, 2.40; crushing strength, 8 000 lb per sq in; sl strength, 1 500 lb per sq in; modulus of rupture, 1 200 lb per sq in; m of elasticity, 3 000 000 lb per sq in. GRANITE: weight, 170; specific g 2.72; crushing strength, 15 000; shearing strength, 2 000; modulus of r 1 500; modulus of elasticity, 7 000 000. LIMESTONE: weight, 170; s gravity, 2.72; crushing strength, 6 000; shearing strength, 1 000; mod rupture, 1 200; modulus of elasticity, 7 000 000. MARBLE: weight, 17 cific gravity, 2.72; crushing strength, 10 000; shearing strength, 1 400; ulus of rupture, 1 400; modulus of elasticity, 8 000 000. SLATE: weigh specific gravity, 2.80; crushing strength, 15 000; modulus of rupture, modulus of elasticity, 14 000 000. TRAP-ROCK: weight, 185; specific g 2.96; crushing strength, 20 000.

The following average relative values are given by A. I. Frye.‡ Th the results of tests made on small cubes of the materials. SANDSTONE: ing strength, 9 000 lb per sq in; GRANITE and GNEISS: crushing st 17 733 lb per sq in. LIMESTONES and MARBLES: crushing strength, 14 per sq in. SLATE: crushing strength, 10 000; ultimate tensional st 3 000; modulus of rupture, 5 000 lb per sq in.

When stones are not tested, Frye recommends the following average for ultimate strengths to be used in determining the safe stresses. SAND crushing strength, 5 000; ultimate tensional strength, 150; modulus of r 1 200 lb per sq in. GRANITE and GNEISS: crushing strength, 12 000; ulus of rupture, 1 600 lb per sq in. LIMESTONES and MARBLES: cr strength, 8 000; ultimate tensional strength, 800; modulus of rupture, 1 per sq in.

The following working unit stresses in pounds per square inch for ston or single blocks of stone are recommended by W. J. Douglass.§ SAND compression, 700; tension (direct and flexural), 75; shear,* 150. GR SYENITE and GNEISS: compression for hard, 1 500; for medium, 1 2 soft, 1 000; tension (direct and flexural), 150; shear, 200. LIMESTONE: pression for hard, 1 000; for medium, 800; for soft, 700; tension (dire flexural), 125; shear, 150. MARBLE: compression for hard, 900; for sof tension (direct and flexural), 125; shear, 150. BLUESTONE FLAGGING: co sion, 1 500; tension (direct and flexural), 200.

4. Compressive Strength of Mortars and Concretes

The Compressive Strength of Lime Mortar. The crushing stre common lime mortar, six months old and composed of 1 part lime to sand by measure, varies from 150 to 300 lb per sq in or from 10.8 to 21 per sq ft. Lime mortar alone should never be used where any but m loads are to bear upon the work, nor where the full loading is to be applied the mortar has had time to harden.

* The values in all cases are as follows: weight, in lb per cu ft; strength, mo rupture and modulus of elasticity, in lb per sq in.

† American Civil Engineers' Pocket Book (1912), page 357.

‡ Civil Engineers' Pocket-Book (1913), page 511.

§ American Civil Engineers' Pocket Book (1912), page 575.

Compressive Strength of Natural-Cement Mortar. The crushing gth* of natural-cement mortar, neat, averaged, for 7 days, 2 010; for s, 2 689; for 3 months, 3 646; and for 6 months, 5 052 lb per sq in. When with 2 parts of standard quartz sand, the mortar averaged in crushing th, for 7 days, 940; for 28 days, 1 390; for 3 months, 1 730; and for ths, 2 012 lb per sq in. For 2 years, an additional increase of 18% and y be assumed for the neat and sanded mortars, respectively, of natural nt.

Compressive Strength of Portland-Cement Mortar. The crushing gth* of Portland-cement mortar, neat, averaged, for 7 days, 5 915; for ys, 7 041; for 3 months, 7 347; and for 6 months, 9 760 lb per sq in. mixed with 3 parts of standard quartz sand, the mortar averaged, in ng strength, for 7 days, 941; for 28 days, 1 290; for 3 months, 1 490; r 6 months, 1 529 lb per sq in. When mixed with 3 parts of Ottawa sand, rtar averaged, in crushing strength, for 7 days, 1 199; for 28 days, 1 796; months, 1 887; and for 6 months, 2 181 lb per sq in. For 2 years, an nal increase of about 16% and 18% may be assumed for the neat and d mortars, respectively, of Portland cement.

tion of Compressive to Tensile Strength of Mortars. While it be stated as a very general guide that the compressive strength of hy-t-cement mortars is from six to ten times the tensile strength, these ratios iable and cannot be used as a reliable basis for calculations. The tensile th of Portland-cement mortars, under normal conditions, increases y during the first few days, the rate of change gradually falling off. In s the tensile strength is generally from one-half to two-thirds of the ulti-strength, which is practically reached in 2 or 3 months. The compressive th, however, continues to increase with age and the rate of increase varies ding to a somewhat different law.

Compressive Strength of Concrete. There are many reasons for riations in the values of the compressive strength of concrete and the pal factors are (1) the quality of the cement, (2) the size and character aggregates, (3) the quantity of the cement to a unit volume of the con-, (4) the manner of mixing, (5) the density of the mixture, (6) the condi-under which it seasons, and (7) its age; and of these various conditions ng the determination of the compressive strength the most important erally the proportions of the different ingredients of the mixture and its Although tables of average values of ultimate crushing strengths of con-are published and are of general value, they may be misleading unless dered with caution. In important operations it is advisable to have the ete tested and to adjust by trial the character and proportions of the in-nts until the required strength is obtained.

m of Specimen for Compression-Tests. For compression-tests of te in general, 4 to 12-in cubes of the mixture have been the standard of test-specimens; but since the advent of reinforced-concrete construc-nd the growth of the importance of determining the elastic properties of te, it has been found that a cylindrical test-specimen gives more definite s than a cube. A common shape of such cylinder is one in which the is about three times the diameter, and the cylinders are not less than 8 in. It is found that the compressive strengths of these cylinders of te are from 10 to 15% less than those of the cubes, but for cylinders of

* m compression-tests made by W. P. Taylor on cylindrical specimens 1 in in height, 1⅛ in in diameter and 1 sq in in cross-section.

still greater slenderness the compressive strengths remain about consta heights up to about seven diameters.

Compression-Tests on Concrete Cubes. From some tests made i for the Boston Elevated Railway Company at the Watertown Arsenal, o cubes of concrete made with five brands of Portland cement, coarse, sand and broken stone up to 2½-in size, having 49.5% voids, the fo average values of the compressive strengths were obtained:

Table XII. Compression-Tests on Concrete Cubes

Mixtures	7 days lb per sq in	1 month lb per sq in	3 months lb per sq in	6 months lb per sq in
1 : 2 : 4	1 560	2 400	2 900	3 820
1 : 3 : 6	1 310	2 160	2 520	3 090

Compression-Tests on Concrete-Cylinders. For cylindrical tes mens of concrete, made under reasonably good conditions as to chara materials and care in mixing, an average compressive strength of abou lb per sq in is usually developed in a 1 : 2 : 4 Portland-cement concrete 1 to 2 months; and of about 1 600 lb per sq in in a 1 : 3 : 6 mixture. the conditions are unusually favorable somewhat higher values than th obtained, but when the materials and workmanship are poor the ultima pressive stresses are lower.

Increase in Compressive Strength of Portland-Cement Concre regard to the increase of compressive strength of Portland-cement c with age, tests show that the ultimate compressive strength is nearly rea 60 days, at which time the strength varies from 80 to 90% of its value in time.

Ultimate Strengths of Natural-Cement Concrete. For natural concrete, the ultimate compressive, tensile and shearing strengths and t ulus of rupture may be taken at about one-half the corresponding va Portland-cement concrete, unless natural cements of known and teste are employed.

Strength of Unreinforced Concrete Columns. Short concrete c of lengths up to 10 or 15 diameters, develop a crushing strength of fro

Table XIII. Compression-Tests on Unreinforced Concrete Colum

Kind of concrete	Average age days	Average ultimate compressive stress lb per sq in
1 : 1 : 2	60	3 600*
1 : 1½ : 3	60	2 270
1 : 2 : 4	60	1 600
1 : 2½ : 5	60	1 200
1 : 3 : 6	60	935
1 : 3½ : 7	60	745
1 : 4 : 8	60	600

* This value was estimated as it was beyond the range of the tests.

less than that for short prismatic or cylindrical specimens. In Table XIII the results obtained by A. N. Talbot * on short, round, unreinforced stone-concrete columns, 12 in in diameter and 10 ft in length. A wet-mixture concrete used, of the different proportions shown, the forms were removed after days and the columns were tested through 60 days.

The values given in the table were deduced from the straight-line formula

$$\text{Ultimate compressive strength, lb per sq in} = \frac{12\,000}{S_a + S_t} - 400$$

which formula

S_a = the ratio of sand to cement
S_t = the ratio of stone to cement

example, in the 1 : 3 : 6 mixture, $S_a = 3$ and $S_t = 6$

Crushing Strength of Concrete Affected by Area of Bearing Surface. Professor Hool states † that if a load is applied over the central part, only, the bearing surface of a concrete test-specimen in compression, the unit load be greater than if it is applied over the entire surface; and this is due to the fact that the outer parts tend to assist the inner part to resist the stress. This shown by tests made on some of the 12-in concrete cubes used in the tests for the Boston Elevated Railway Company and referred to in the preceding paragraphs. Thirty-six of these concrete cubes were crushed by applying load over the entire upper bearing-surface of 144 sq in and an equal number similar concrete cubes were then crushed by applying the stress over a smaller 10 by 10 in, or 100 sq in. After this, the cubes of a third set were crushed the application of the stress over the still smaller area, 8 by 8¼ in, or 66 in. The tests of the second set gave unit crushing strengths 12% higher than first, and those of the third set unit crushing strengths 28% higher than first.

Working Stress for Bearing on Concrete. "When compression is applied surface of concrete of at least twice the loaded area, a stress of 32.5% of compressive strength may be allowed."‡

Working Stress for Axial Compression on Concrete. "For concentric compression on a plain concrete column or pier, the length of which does not exceed 12 diameters, 22.5 % of the compressive strength may be allowed." * (For the strength of reinforced-concrete columns, see Chapter XXIV, page 945.)

Recommended Ultimate Compressive Strengths of Portland-Cement Concrete.‡ Table XIV, of ultimate compressive strengths of concrete of different mixtures gives the values recommended by the American Society for Testing Materials, even though occasional tests show higher results. The values given are recommended as the maximum ultimate unit compressive strengths that should be used in design and on which the permissible working stresses should be based as a proper percentage of the same. The report referred states, also, that "in selecting the permissible working stresses to be allowed on concrete, we should be guided by the working stresses usually allowed for other materials of construction, so that all structures of the same class, but composed of different materials, may have approximately the same degree of safety." (For working stresses for concretes, masonry, etc., see this chapter, pages 265 to 276.)

* See University of Illinois Bulletin, No. 20, 1907, and Engineering News, Sept. 26,

† See Reinforced Concrete Construction, Vol I., page 18, by George A. Hool.

‡ Report of Committee on Concrete and Reinforced Concrete, of the American Society for Testing Materials, Nov. 20, 1912.

Table XIV. Ultimate Compressive Strengths of Different Mixtures of Portland-Cement Concretes

Aggregates	Mixtures				
	1 : 1 : 2 lb per sq in	1 : 1½ : 3 lb per sq in	1 : 2 : 4 lb per sq in	1 : 2½ : 5 lb per sq in	1 : 3 lb sq
Granite, trap-rock..........	3 300	2 800	2 200	1 800	1
Gravel, hard limestone and hard sandstone...........	3 000	2 500	2 000	1 600	1
Soft limestone and sandstone.....................	2 200	1 800	1 500	1 200	1
Cinders	800	700	600	500	

Effect of Consistency on the Crushing Strength of Concrete. Co that is mixed fairly dry and tamped until the moisture is brought to the su develops a somewhat greater compressive strength than concrete mixed more water. From a large number of tests * average compressive streng wet, plastic and dry concretes were determined. The age of the concret 1 year and 8 months, and five brands of cements were used. The mean pressive strengths were, for the wet concrete, 2 130; for the plastic, and for the dry, 2 350 lb per sq in.

In another series of tests † greater differences appeared. At the ag month the mean compressive strengths in pounds per square inch were, f wet concrete: granite, 3 155; gravel, 2 300; limestone, 4 195. For the m concrete: granite, 4 090; gravel, 3 545; limestone, 2 975. For the dam crete: granite, 4 520; gravel, 4 610; limestone, 4 365. At the end of 3 m the values for the granite aggregates were, for the wet concrete, 4 755; f medium, 4 990; and for the damp, 5 445.

Effect of Size of Stone on the Compressive Strength of Concrete may be stated, generally, that the use of stones of a maximum size cons with convenience generally results in a maximum compressive strength concrete. Stones of the larger sizes are generally more uniformly grade the smaller stones, and consequently grade better with the sand and give g strength. From tests ‡ made by W. B. Fuller, the average compressive stre at 140 days, of 1 : 9 concrete, were, for maximum size of stone ½ in., 1 per sq in; for 1-in stone, 1 150 lb per sq in; and for 2¼-in stone, 1 400 sq in.

Comparison of Compressive Strengths of Gravel and Stone Conc Concretes made with broken stone have, generally, a somewhat greate pressive strength than those made with gravel. From tests made by E. C the average compressive strength at 30 and 180 days, of concrete mad 1½-in maximum-size broken stone, was 20% greater than that of concrete of gravel of about the same size, the percentage of voids being nearly the 40% voids for the gravel and 47.4% voids for the broken stone. The a difference at 12 months, however, was reduced to 9%.

* Made for G. W. Rafter. See "Tests of Metals," 1898.
† Made in 1908. See Bulletin No. 344, United States Geological Survey.
‡ See Trans. Am. Soc. C. E., Vol. 59, 1907.

Effect of the Strength of the Aggregate on the Compressive Strength of Concrete. The compressive strength of trap-rocks, granites and most [illegible]stones is relatively so great that it cannot reduce the strength of the concrete itself. Some sandstones, however, have a much lower average compressive strength, and if they are friable and soft may lower relatively the final strength of the concrete. A concrete of low strength results from using cinders for the aggregate.

Building Laws for Working Loads on Masonry.* As previously mentioned (page 265) the building codes of most cities specify working loads to be used for masonry and as shown in Table II (page 267) these loads vary greatly. It is important, therefore, that the architect should be acquainted with the municipal [illegible] by which the construction of his building is governed. As building laws and regulations are constantly changing this information should be obtained from the code itself, care being taken that the latest edition and all supplements are consulted. A few requirements, peculiar to the codes in which they are [illegible], will be cited.

The Chicago code (1916) gives for eight classes of brickwork bearing values ranging from 100 lb per sq in for common brick with good lime mortar to 350 lb per sq in for paving brick with 1 to 3 Portland-cement mortar. This code discriminates between concrete mixed by hand and by machine, values of from [illegible] to 350 lb per sq in being given for hand-mixed concrete and from 300 to [illegible] per sq in for the same mixture if mixed by machine. The values in the [illegible] code are exceptionally low, common brick laid in lime mortar being [illegible] but 3 tons and concrete in foundations but 4 tons per sq ft. The [illegible]ville code introduces values for "Louisville-cement mortar." The practice [illegible] values of local material is to be commended. The Denver code gives [illegible] of 3 tons per sq ft on common brick with coal-dust in lime mortar, 3 tons [illegible] hollow tile in cement mortar and 8 tons for terra-cotta, solid, in cement. The Seattle code gives for the allowable compressive stress of mass concrete [illegible] of its compressive strength in twenty-eight days. The building code recommended by the National Board of Fire Underwriters is followed by a number of cities. This code includes in its list of allowable compression values, 1000 lb per sq in for Portland-cement grout, neat, and 1500 lb per sq in for Portland-cement grout, neat, not over ½ in thick, between steel members in foundations. For natural-cement concrete values are given of 125 lb per sq in for a 1 : 2 : 4 mixture and 80 lb per sq in for a 1 : 2 : 5 mixture. The average ultimate compressive strength for terra-cotta blocks designed to be normally laid with the cells vertical, and which are tested with the cells in that position, must not be less than 1200 lb per sq in. The allowable working stress on such blocks must not exceed 120 lb per sq in. The average ultimate compressive strength for terra-cotta blocks designed to be normally laid with the cells horizontal, and which are tested with the cells in that position, must not be less than 800 lb per sq in. The allowable working stress on such blocks must not exceed 80 lb per sq in. Hollow building blocks may be filled solidly with Portland-cement concrete or cement mortar to increase the stability and to aid in distributing the load, but the allowable working stress on such blocks must not be greater than that permitted for unfilled blocks.

* [illegible]ed from valuable data from Robins Fleming. See, also, pages 265 to 267 and Table II, page 267.

CHAPTER VI

FORCES AND MOMENTS

BY

MALVERD A. HOWE

PROFESSOR OF CIVIL ENGINEERING, ROSE POLYTECHNIC INSTITUTE

1. Composition and Resolution of Forces

Composition and Resolution of Forces. Imagine a round ball plac plane, frictionless surface at A (Fig. 1), the surface being perfectly level, the ball has no tendency to move until som is applied to it. If, now, the force, P, is to the ball in the direction indicated by the the ball will move in that direction. If, ins one force only, two forces, P and P_1, are ap the ball, it will not move in the direction o of the forces, but will move in the direction RESULTANT of these forces, or in the direct If the magnitudes of the forces P and indicated by the lengths of the lines, the complete the parallelogram $ABDC$, the d DA represents the direction and magnitu single force which has the same effect on as that resulting from the two forces P and P_1. If, in addition to forces P and P_1, the third force, P_2, is applied, the ball will move direction of the resultant of all three forces, and this resultant is obta completing the parallelogram $ADEF$, of which the resultant DA and th force P_2 are two adjacent sides. The diagonal R of this second parallelogram is the resultant of all three forces, and the ball will move in the direction Ae. In the same way the resultant of any number of forces may be found. Again, suppose a ball, whose weight is indicated by the length of the line W (Fig. 2), is suspended by two inclined cords. What are the magnitudes of the pulls or stresses which are developed in the cords and which keep the ball suspended at the point A? This is the converse of the last case. Instead of finding the diagonal or the resultant, the diagonal, which is the line W, is given, and the sides of the parallelogram are to be found. To find these the lines representing the directions of P and P_1 are prolonged and from B lines parallel to them are drawn to complete the parallelogram. Then CA is the required magnitude of the stress in cord P, and BC of that in cord P_1. Thus one fo have the same effect as many, or many the same effect as one.

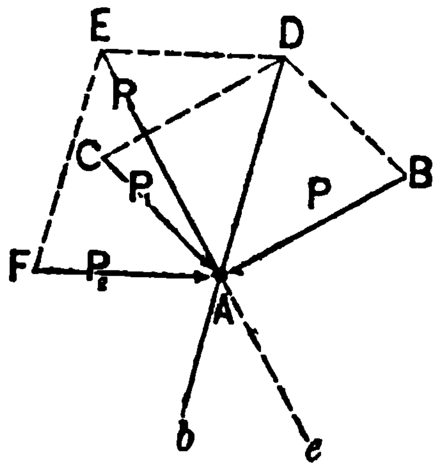

Fig. 1. Composition of Forces

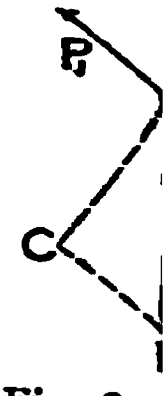

Fig. 2.
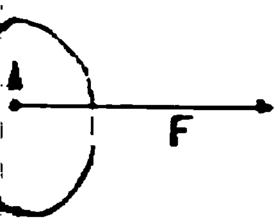
tion of

Forces Represented by Straight Lines. In considering the action o it is convenient to represent them graphically by straight lines with heads, as in Fig. 3. The length of the line, if drawn to a scale of pound sents the MAGNITUDE OF THE FORCE in pounds; the position of the line i

...OF ACTION; the arrow-head indicates its SENSE or the direction in which ...; and the point A its POINT OF APPLICATION. Thus the magnitude, direction and point of application are indicated and the force is completely represented.



...Force Represented ...a Straight Line

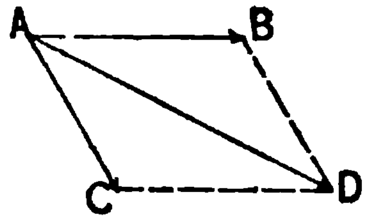


Fig. 4. Parallelogram of Forces

Parallelogram of Forces. If two forces applied at one point are represented in magnitude and direction by two ...t lines inclined to each other, their resultant is the diagonal of the ...ELLOGRAM formed on those lines. Thus, if the lines AB and AC (Fig. 4) ...nt two forces acting at a point A, to find the force which will have the ...effect as the two forces, the parallelogram ...C is completed and the diagonal AD drawn. ...line represents the RESULTANT of the two ... When the two given forces act at right... to each other, the magnitude of the resultant ...l to the square root of the sum of the ...s of the magnitudes of the other two forces.

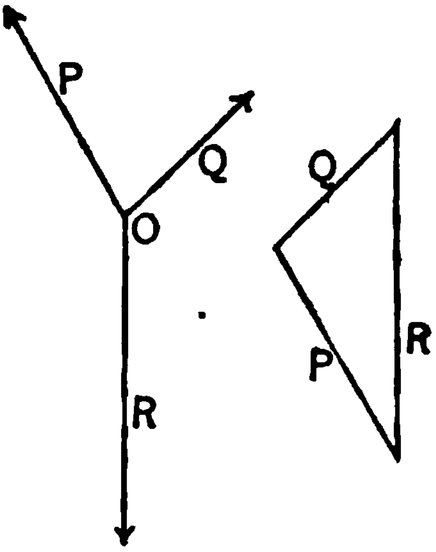

Fig. 5. Triangle of Forces

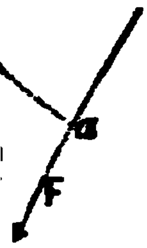
...ngle of Forces. If three forces acting at ...t are represented in magnitude and direction ... sides of a TRIANGLE taken in order, they are ...ibrium. Let P, Q and R (Fig. 5) represent ...forces acting at the point O. If a triangle ... drawn, like that shown at the right in Fig. ...ing sides respectively parallel to the direc... ...f the forces and taken in the same order, ...rces are in equilibrium. If such a triangle cannot be drawn, the forces ...t in equilibrium.

...**Polygon of Forces.** If any number of forces acting at a point can ...resented in magnitude and direction by the sides of a POLYGON taken ...er, they are in equilibrium. This follows directly from the preceding ...m.

2. Moments of Forces

...**ments.** In considering the stability of structures and the strength of ...ks, we are often obliged to take into consideration the moments of ...ces acting on a structure or on some part of a structure; and a knowledge of the general PRINCIPLES OF MOMENTS is essential to the proper understanding of these subjects. When we speak of the MOMENT OF A FORCE, we must have in mind some fixed point or line with respect to which the moment is taken. The moment of a force with respect to any given point, or CENTER OF MOMENTS, is the product of the magnitude of the force and the perpendicular distance from the point to the LINE OF ACTION of the force; or, in other words, the moment of a force is the product of the magnitude of the force by ... with which it acts. Thus if we have the force F (Fig. 6), and wish to ...ne its moment with respect to the point P, we determine the per...lar distance Pa, between the point and the line of action of the force, ...tiply it by the magnitude of the force. For example, if the magnitude



... Moment ...a Force

of the force F is 500 lb and the distance Pa is 2 in, the moment of t with respect to the point P is 500 lb × 2 in = 1 000 in-lb.*

Parallel Forces. If any body is in a state of rest or equilibrium u action of parallel forces, the sum of the forces acting in one direction eq sum of the forces acting in the direction. Thus if we have the forces P^1, P^2, P^3 and P^4 acting on AB (Fig. 7), in a direction opposite of the forces P_1, P_2 and P_3, then, if is in equilibrium, the sum of the fo P^2, P^3 and P^4 must equal the sum forces P_1, P_2 and P_3.

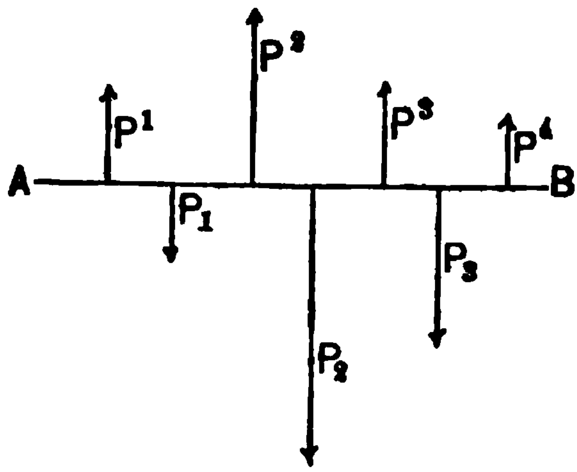


Fig. 7. Algebraic Sum of Unlike Parallel Forces

Parallel Forces Opposite in Ch If any number of parallel forces, acting in the same direction, act on if the body is in equilibrium, the sum moments of the forces tending to t body in one direction about an point is equal to the sum of the moments of the forces tending to tu the opposite direction. Let F_1, F_2 and F_3 (Fig. 8) represent three forces acting on the rod AB. If the rod is in equilibrium, the sum forces F_2 and F_3 is equal to F_1. Also, if we take the end of the rod, A, for the center of moments, the moment of F_1 is equal to the sum of the moments of F_2 and F_3 about that point, because the moment of F_1 measures the tendency to turn the rod CLOCKWISE, and the sum of the moments of F_2 and F_3 measure the tendency to turn the rod CONTRA-CLOCKWISE, and there is no more tendency to turn the rod one way than the other. For example, let the magnitude of forces F_2, F_3 each be represented by 5 force-units, the distance Aa by 2 length-units and the distance AB by 4 length-units. The magnitude of the force F_1 must equal the sum of the magnitudes of the forces F_2 and F_3, or 10 force-units, and its with respect to any point in the plane of the forces must equal of the moments of F_2 and F_3 with respect to the same point. If we t the center of moments, the moment of $F_3 = 5 \times 2 = 10$, and of $F_2 = 5$ › Their sum equals 30; hence the moment of F_1 must be 30. Dividing ment 30 by the force $F_1 = 10$ force-units, we have for the arm, 3 length- the force F_1 must act at a distance of 3 units from A to keep the rod in rium. If we take b as the center of moments, the force F_1 has no mo the length of its lever-arm is zero; and, for equilibrium, the moment of b must equal the moment of F_3 about the same point; or, as in this magnitudes of the forces F_2 and F_3 are equal, they must both be appli same distance from b, showing that b must be half-way between a and demonstrated before.

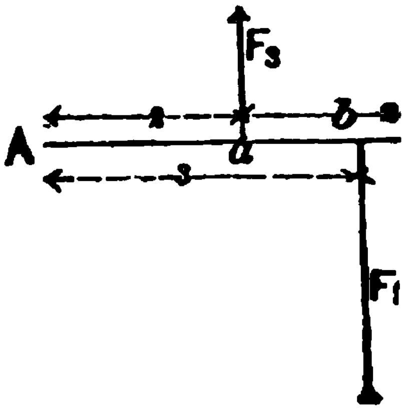

Fig. 8. Algebraic Sum ments of Unlike Paral

Three Parallel Forces. THE PRINCIPLE OF THE LEVER. This pri based upon the two preceding propositions and is of great importance

* The expressions POUND-FEET and POUND-INCHES are often given to thes to distinguish them from FOOT-POUNDS and INCH-POUNDS, by which WORK ar are measured.

...re. If a body is in equilibrium under the action of three parallel forces ...g in the same plane, each force is proportional to the normal distance be... the other two. Thus, if, as in Figs. 9, 10 and 11, three forces, P_1, P_2 and

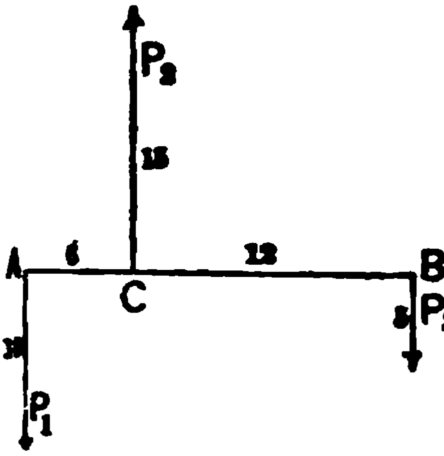

Fig. 9. Principle of the Lever

...t on the rod AB, in order that it may be in equilibrium, the following ...s must obtain between the magnitudes of the forces and the distances ...en their points of application;

$$\frac{P_1}{CB} : \frac{P_2}{AB} : \frac{P_3}{AC}$$

$$P_1 : P_2 : P_3 :: CB : AB : AC$$

...is the case of the COMMON LEVER and shows the method of determining ...weight a given lever will raise. The proportion is also true for any ar...ment of the forces (as shown in Figs. 9, 10 and 11), provided, of course, ...ces are lettered in the order shown in the ...s.

...example, let the distance AC be 6 in and the ...ce CB be 12 in. If a weight of 500 lb is ...d at the point B, how much will it raise at ...er end and what support will be required at ... 10)?

...ying the rule just given, we have the pro...:

$P_3 : P_1 :: AC : CB$ or $500 : P_1 :: 6 : 12$

$P_1 = 1\,000$ lb; or 500 lb applied at B will ...00 lb resting on or suspended at A. The ...ing force at C must, by the principles of PARALLEL FORCES IN ...RIUM, be equal to the sum of the forces P_1 and P_3, or 1 500 lb in ...e.

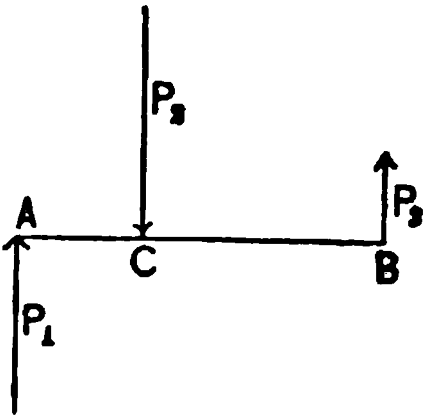

Fig. 11. Principle of the Lever

2. Center of Gravity

...al Principles. The LINES OF ACTION of the force of gravity converge ... the center of the earth; but the distance of the center of the earth from ...es which we have occasion to consider, compared with the size of those ...is so great, that we may consider the lines of action of the forces as ... The number of the forces of gravity acting upon a body may be con...as equal to the number of particles composing the body. The CENTER OF ... of a body may be defined as the point through which the resultant of ...lel forces of gravity, acting upon the body, passes for every position ...may. If a body is supported at its center of gravity and turned about

that point, it will remain in equilibrium in all positions. The resultant parallel forces of gravity acting upon a body is obviously equal to the w OF THE BODY; and if a force, equal in magnitude to the resultant, is a acting in a line passing through the center of gravity of the body, an direction opposite to that of the resultant, the body will be in equilibriu

Center of Gravity of a Straight Line. The word LINE here m material line whose transverse section is very small, such as a very fin The center of gravity of a straight line or rod of uniform size and mat at its middle point. This proposition is too evident to require demonst

The Center of Gravity of the Perimeter of a Triangle is at the of the circle inscribed in the triangle formed by the lines joining the points of the sides of the given triangle. let ABC (Fig. 12) be the given triangle. the center of gravity of its perimeter, fi middle points, D, E and F, and connect t straight lines. The center of the circle in in the triangle formed by these lines will center of gravity sought.

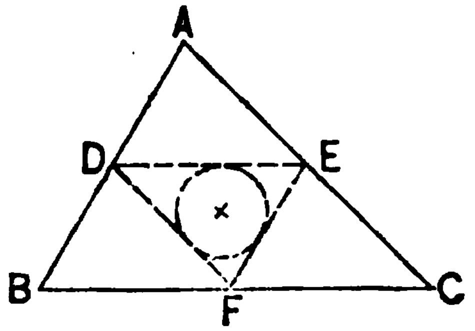

Fig. 12. Center of Gravity of Perimeter of Triangle

Center of Gravity of Symmetrical The center of gravity of a line which metrical with reference to a point is point. Thus the center of gravity of cumference of a circle or of an ellipse is at the geometrical center of the The center of gravity of the perimeter of an equilateral triangle, regular polygon, is at the center of the inscribed circle. The center of gr the perimeter of a square, rectangle, or parallelogram is at the interse the diagonals of those figures.

Center of Gravity of a Surface. A SURFACE here means a very th or shell. If a surface can be divided by a line into two symmetrical hal center of gravity will be on that line; if it can thus be divided by two li center of gravity will be at their intersection.

Center of Gravity of Regular Figures. The center of gravity of face of a circle or an ellipse is at the geometrical center of the figu equilateral triangle or regular polygon, at the center of the inscribed a parallelogram, at the intersection of the diagonals; of the surface of or of an ellipsoid of revolution, at the geometrical center of the body the convex surface of a right cylinder, at the middle point of the a cylinder.

Center of Gravity of Irregular Figures. Any figure bounded b lines may be divided into rectangles and triangles, and, the center of each part being found, the center of gravity of the whole figure may mined by treating the centers of gravity of the separate parts as parti weights are proportional to the areas of the parts they represent. (See

Center of Gravity of Triangles. To find the center of gravit angle, draw a line from each of two angles to the middle of the opp The intersection of the two lines is the center of gravity.

Center of Gravity of Quadrilaterals. To find the center of gra quadrilateral, draw the diagonals, and from that end of each diagon farthest from the intersection, lay off, toward the intersection, the its shorter segment. The two points thus formed, together with t

...ation, will form a triangle whose center of gravity is that of the quad-...al. Thus, let Fig. 13 be a quadri-...al whose center of gravity is to be ...d. Draw the diagonals AD and BC, ...from A lay off $AF = DE$, and from B ...off $BH = CE$. From E draw a line to ...middle of FH, and from F a line to the ...dle of EH. The point of intersection ...these two lines is the center of gravity ...the quadrilateral. This is a method ...monly used for finding the centers of ...vity of the voussoirs of an arch.

...ble of Centers of Gravity. Let a ...a line drawn from the vertex of a figure ...the middle point of the base, and D the distance from the vertex to the center ...gravity of the figure. Then (Fig. 14):

In an isosceles triangle	$D = \frac{2}{3} a$
In a segment of a circle, vertex at center of circle	$D = \dfrac{\text{chord}^3}{12 \times \text{area}}$
In a sector of a circle, vertex at center of circle	$D = R \times \dfrac{2 \times \text{chord}}{3 \times \text{arc}}$
In a semicircle, vertex at center of circle	$D = \dfrac{4R}{3\pi} = 0.4244\,R$
In a quadrant of a circle	$D = \frac{3}{5} R$
In a semiellipse, vertex at center of circle	$D = 0.4244\,a$
In a parabola, vertex at intersection of axis with curve	$D = \frac{3}{5} a$
In a cone or pyramid	$D = \frac{3}{4} a$

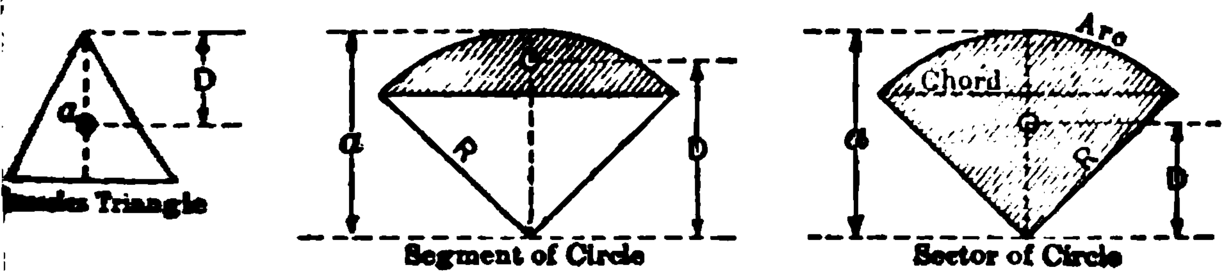

Fig. 14. Center of Gravity of Triangle, Segment and Sector

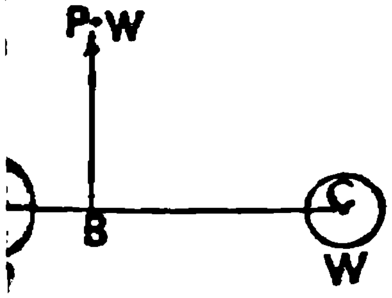
...frustum of a cone or pyramid, let h = the height of the complete cone or pyramid, h_1 = the height of the frustum, and let the vertex be at the apex of the complete cone or pyramid; then,

$$D = \frac{3\,(h^4 - h_1^4)}{4\,(h^3 - h_1^3)}$$



...15. Center of Gravity of ...Two Heavy Particles

Center of Gravity of Two Heavy Particles. Let P be the weight of a particle at A (Fig. 15), and W that of a particle at C. The center of gravity is at some point, B, on the line joining A ... The point B must be so situated that if the two particles were held ...by a stiff wire and supported at B by a force equal in magnitude to ...of P and W they would be in equilibrium. The problem then is

solved by the PRINCIPLE OF THE LEVER, and we have the proportion Three Parallel Forces. The Principle of the Lever),

$$P + W : P :: AC : BC$$

or

$$BC = \frac{P \times AC}{P + W}$$

If $W = P$, then $BC = AB$, or the center of gravity will be half-way betwee two particles. This problem is of great importance and has many pra applications.

Center of Gravity of Several Heavy Particles. Let W_1, W_2, W_3 and W_5 (Fig. 16) be the weights of the particles. Join W_1 and W_2 by a str line and find their center of gravity A, as i preceding problem. Join A with W_3 and fin center of gravity B, which will be the cent gravity of the three weights W_1, W_2, W_3. Pr in the same way with each weight. The last c of gravity found will be the center of gravity the particles. In both of these cases the lines jo the particles are supposed to be horizontal lin else the horizontal projections of the straight which join the points.

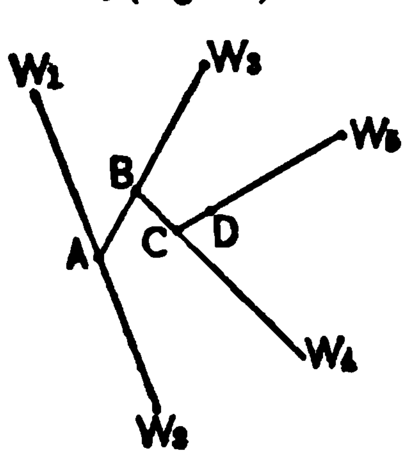


Fig. 16. Center of Gravity of Several Heavy Particles

Center of Gravity of Compound Sec Found by Moments. To determine the str of a beam having an unsymmetrical cross-secti is first necessary to determine the distance of the center of gravity of this s from the upper or lower surface of the beam. Various other computa also, involve finding the center of gravity of an irregular figure, so th problem is one of practical importance. If the figure of which the cen gravity is to be found can be divided into parts which are themselves r figures, the readiest and simplest method of finding the distance of the of gravity from one edge of the section is by means of MOMENTS. To explain this method assume a T-shaped section of uniform thickness, hinged on a wire XX, as in Fig. 17. The T section is made up of two rectangles, one forming the flange, the other the web. The center of gravity of each rectangle is at its own center of figure and may be readily found. If the T section is placed horizontally, as in the figure, the axis XX being fixed, it will immediately, by the force of gravity, revolve about the axis until it becomes vertical, and the sum of the moments of the forces causing the revolution is $A' \times d' + A'' \times d''$, A' representing the weight of the web and A'' the weight of the flange. To hold the T s in a horizontal position, there must be a moment of some force acting opposite, or upward, vertical direction and just equal to the sum two moments causing revolution downwards. If the force A, of this m tending to cause revolution upward, is equal to the weight of the entire tion, it must be applied at the center of gravity of the entire figure to m moment just equal to the sum of the moments of the two downward

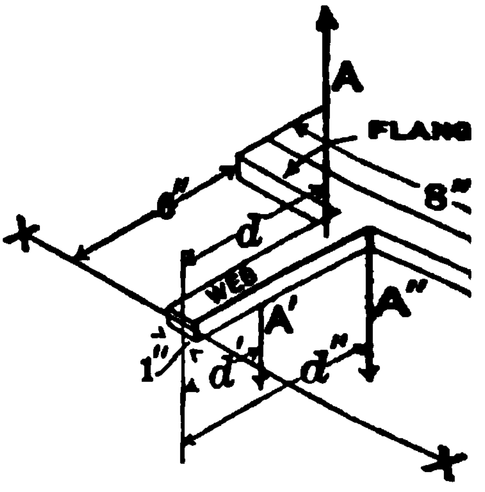

Fig. 17. Center of Grav Compound Sections by Mo

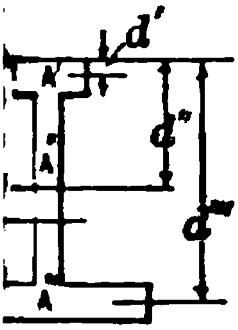
...moment of A is $A \times d$, therefore d is the distance from the end of the web, ...n the axis XX, to the center of gravity of the entire figure. Therefore, ...$A \times d = A' \times d' + A'' \times d''$,

$$d = \frac{A' \times d' + A'' \times d''}{A} \tag{1}$$

...weight of any homogeneous material of uniform thickness is proportional ...area, A, A' and A'' may be used to represent areas as well as weights. ...sing formula (1) as a rule, we have:

...ter of Gravity of Compound Figures. The distance of the center of ...y of a compound figure from any line of reference is equal to the sum of ...ducts, obtained by multiplying the area of each of the simple parts into ...the compound figure is divided by the distances of its center of gravity from the line of reference, divided by the area of the entire figure. This rule applies to any compound figure.



...8. Center of Gravity of Tees, Angles, ...nels, etc.

Example I. Assume that the T section shown in Fig. 17 has the dimensions indicated. Then A' equals 6, A'' equals 8, and A equals 14 sq in; and d' equals 3 and d'' equals $6\frac{1}{2}$ in. The sum of the products of A' by d' and ...d'' is 18 + 52 or 70 sq in × in, and this divided by 14 sq in, the area ...entire figure, gives 5 in for the distance d. The distance d of the center ...ity from the top of the webs, in each of the figures shown in Fig. 20, ...d by the following formula:

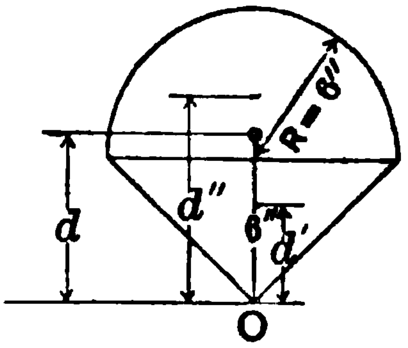


Fig. 19. Center of Gravity of Irregular I Section

$$d = \frac{\text{area of the web or webs} \times d'/2 + \text{area of flange} \times d''}{\text{area of the web or webs} + \text{area of flange}} \tag{2}$$

...section like that shown in Fig. 18, in which A', A'' and A''' represent the ...of the respective rectangles, the distance d of the center of gravity from ...p may be found by the formula

$$d = \frac{A' \times d' + A'' \times d'' + A''' \times d'''}{A' + A'' + A'''} \tag{3}$$

...ple II. To show the application of the rule for finding the center of ...y of compound figures, take the one shown in Fig. 19. The distance d

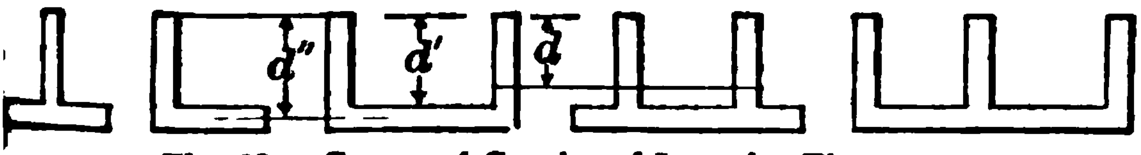

Fig. 20. Center of Gravity of Irregular Figures

...center of gravity of the entire figure from the vertex O is found as follows: ...a of the triangle is 36 sq in and of the semicircle 56.5 sq in. From the ...of Centers of Gravity (page 293) the distance of the center of gravity of ...this triangle from the vertex is two-thirds its height, which gives 4 in as

the value for d'. The center of gravity for a semicircle is 0.4244 R f
base, so that d'' equals 8.54 in. Then,

$$d = \frac{36 \times 4 + 56.5 \times 8.54}{36 + 56.5} = 6.77 \text{ in}$$

This method of finding the center of gravity is similar to that expla
Chapter IX for finding the supporting forces or reactions. In the latt
however, the problem is to find the balancing forces instead of the lever-

Additional Methods of Determining Graphically the Center of (of Irregular Plane Figures.* The center of gravity may be obtained ically by means of the FORCE-POLYGON and the EQUILIBRIUM-POLYGO figure or section considered, Fig. 21, is divided into parts whose cer

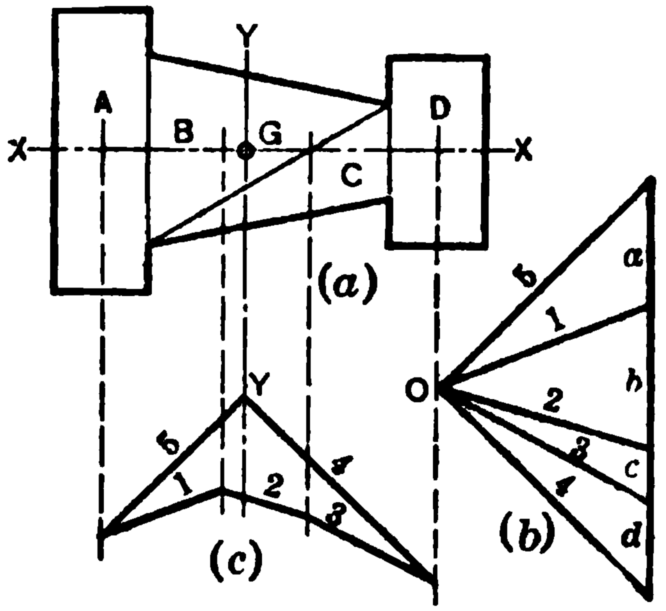

Fig. 21. Center of Gravity Determined Graphically.

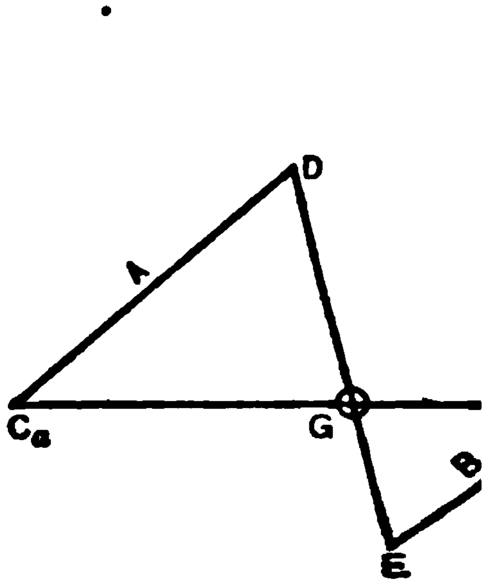

Fig. 22. Center of Gravity De Graphically. Second M

gravity can be located and areas calculated. The force-polygon (b) and rium-polygon (c) are drawn. The figure (a) is divided into rectangles angles, A, B, C and D, and vertical lines are drawn through their ce gravity. In (b) the vertical lines a, b, c and d are respectively proport length to the areas A, B, C and D. The pole, O, is located by the inters lines drawn at angles of 45° from the extremities of the line $abcd$. T 1, 2, 3, 4 and 5 are drawn from o, as shown, and the corresponding para drawn in (c). (See Figs. 3 and 5, pages 299 and 300; Figs. 12 to 1 314 to 320; and page 345.) The vertical line through Y, produced is a GRAVITY-AXIS and its intersection G with the horizontal gravity-axi the center of gravity of the figure. If the figure is not symmetric XX a second gravity-axis may be found by turning the figure through repeating the construction. The intersection of the two gravity-axes w center of gravity of the figure. ANOTHER METHOD is shown in Fig. the centers of gravity of two areas A and B be at the points C_a and C_b ively. From C_a the line C_aD is drawn in any direction, and its length on some given scale the area A. From C_b the line C_bE is drawn par and its length on the same scale represents the area B. The intersecti line joining D and E with C_aC_b is at the center of gravity of the areas For three areas A, B and C, the construction can be repeated by con and B as a single area; and so on for any number of areas.

$$T \times ab = W \times t/4$$

...he width of the pier.

...not from this equation determine the dimensions of a pier to resist a ...rust, because we have the distance ab, t and W, all unknown quantities. ...e must first assume a tentative size for the pier, find the length of the ...nd see if the MOMENT OF THE WEIGHT of the pier is equal to the MO-... THE THRUST. If it is not we must assume another size for the pier. ...t of fact the steps of the problem usually present themselves in the

* See, also, Chapter XXXI, Section 2, Vaults.

inverse order, the pier or buttress being given and the determinati stability being required. The size of the pier or buttress is usually fi mined rather from the architectural exigencies of the design than engineering requirements for the stability of the structure. If upon i tion these are not in accord, it is the duty of the designers to use their i in seeing that both conditions are fufillled.

The Stability of Piers and Buttresses. When it is desired to d if a given pier or buttress is capable of resisting a given thrust, the pro be solved GRAPHICALLY in the following mann *ABCD* (Fig. 2) represent a pier which sustains thrust *T* at *B*. To determine whether the pier w sustain this thrust, we proceed as follows:

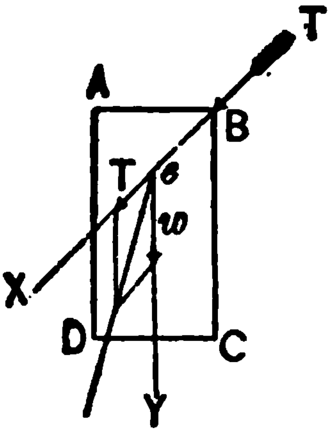

Fig. 2. Graphical Determination of Thrust on Pier

Draw the indefinite line *BX* in the directio thrust. Through the center of gravity of the pi in this case is midway between *AD* and *BC*, dra tical line intersecting the line of the thrust at force may be considered to act anywhere along i action, we may consider that the thrust and th act at the point *e*. The resultant of these two obtained by laying off the thrust *T* from *e* on *eX* weight of the pier *W*, from *e* on *eY*, both to the s of so many pounds to the inch, completing the ogram and drawing the diagonal. If this diagonal, prolonged, cuts of the pier at less than one-third the width of the base from t edge, the pier is generally considered unstable and its dimensions are (See Chapter IV, Theorem of the Middle Third.)

The Stability of Buttress with Offsets. THE STABILITY OF A PIE increased by adding to its weight by placing some heavy material o example, or by increasing its width at the base by means of OFFSE Fig. 3. Figs. 3 and 4 show the method of determining the stability tress with offsets. The first step is to find the vertical line passing th center of gravity of the whole pier. This is best done by dividing th into quadrilaterals, as *ABCD*, *DEFG* and *GHIK* (Fig. 3), finding the gravity of each quadrilateral by either the method of diagonals or tr explained in Chapter VI, and then measuring the perpendicular dist X_2, X_3 from the different centers of gravity to the line *KI*. (See, also VIII, page 313).

Multiply the area of each quadrilateral by the distance of its cent ity from the line *KI* and add together the areas and the products. I sum of the products by the sum of the areas and the result will be th of the center of gravity of the whole buttress from *KI*. This distance by X_0. This calculation is a practical application of the theorem in that the MOMENT OF THE RESULTANT of any number of forces abo point is equal to the SUM OF MOMENTS of the individual forces about

Example 1. Let the buttress shown in Fig. 3 have the dimensi Then the areas of the quadrilaterals and the distances from their gravity to *KI* are as follows:

First area	=	35 sq ft	$X_1 = 0'.95$	First area $\times$ X_1 =
Second area	=	23 sq ft	$X_2 = 2'.95$	Second area $\times$ X_2 =
Third area	=	11 sq ft	$X_3 = 4'.95$	Third area $\times$ X_3 =
		Total area, 69 sq ft		Total moments,

The sum of the moments of the areas is 155.55, and dividing this by the total , we have 2.25 as the distance X_8. Measuring this to the scale of the draw- from KI, we have a point through which the vertical line passing through the ter of gravity must pass.

The line, passing through the center of gravity of the buttress, can be found PHICALLY, also, by the method of the EQUILIBRIUM POLYGON (Fig. 3). (See

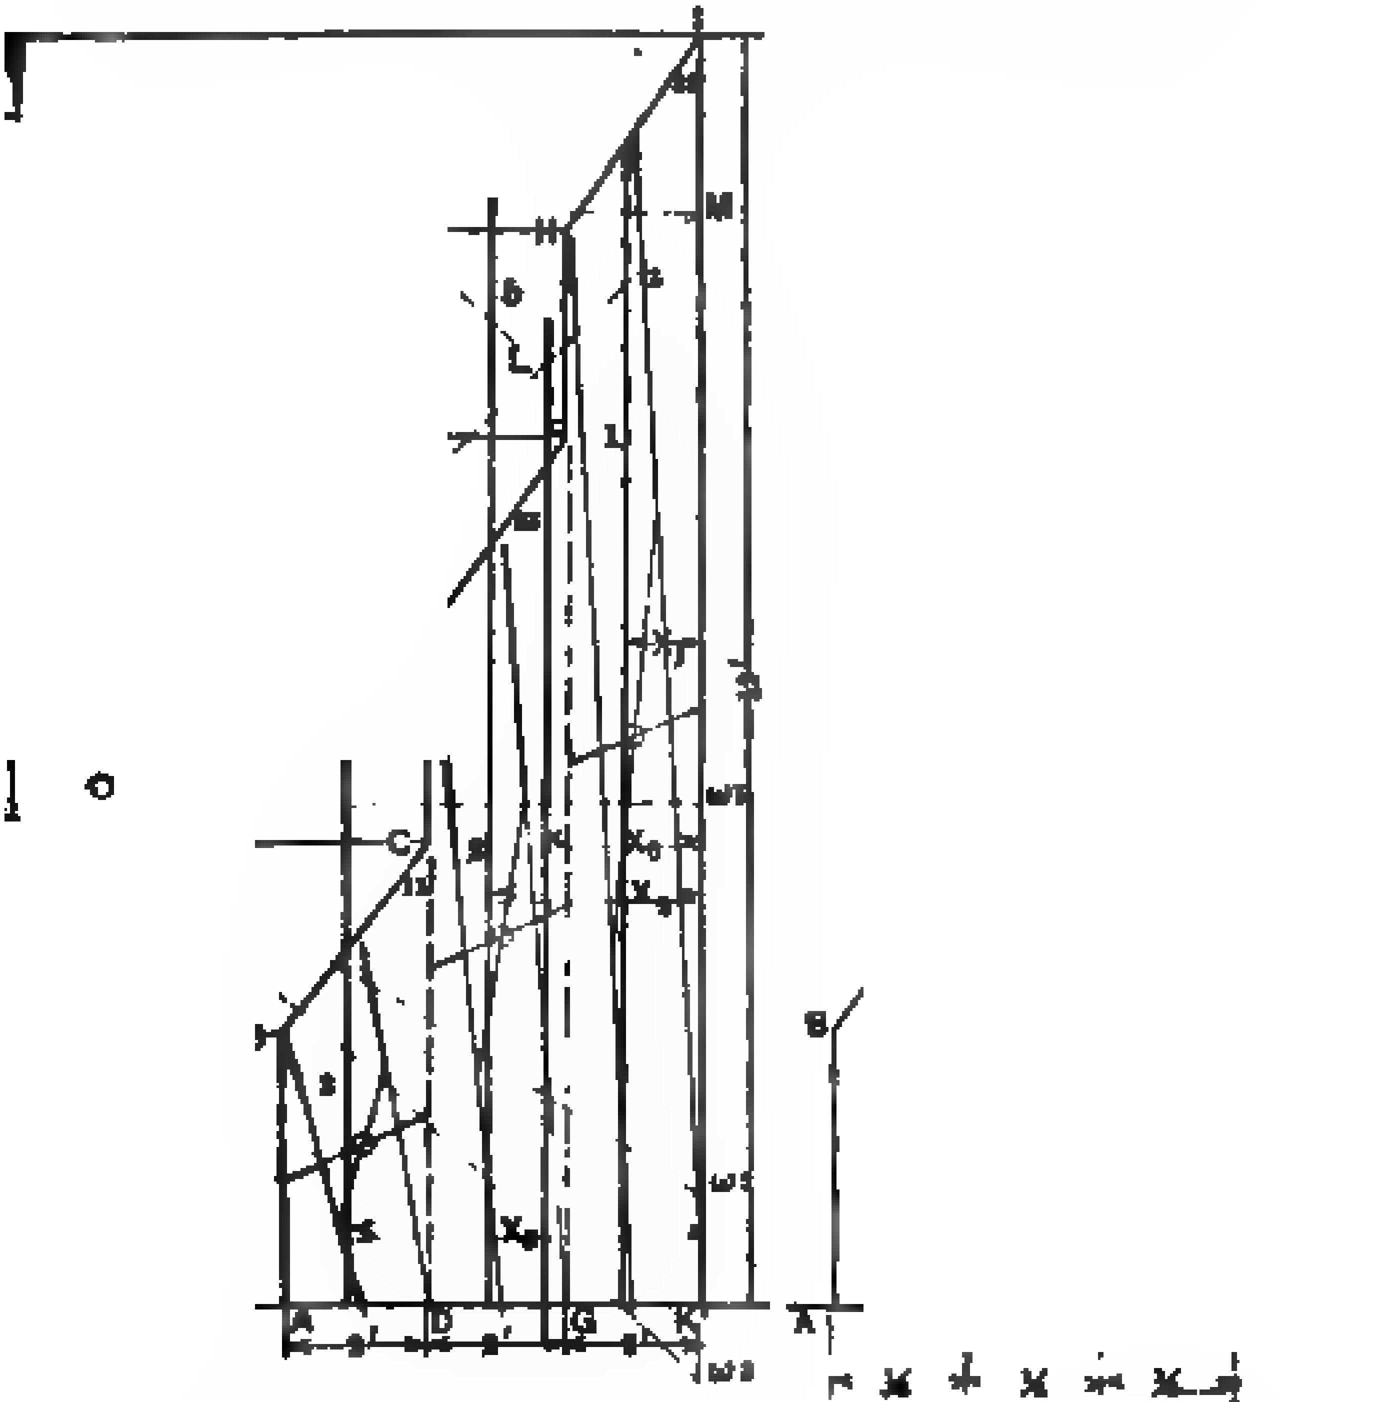

Fig. 3. Buttress with Offsets

Fig. 4. Resultant Thrust on Buttress with Offsets

296 and 314 to 320.) In order to do this, lay off at any convenient , beginning at some convenient point M, Mw 1, w 1 w 2, and w 2 w 3, the s of the various quadrilaterals composing the buttress. Through the center avity of each quadrilateral draw a vertical (green) line. Draw the lines and w 3 O, intersecting at some conveniently chosen POLE-POINT, O, Ow 1 and Ow 2. Through a, where MO intersects the vertical) line drawn through the center of gravity of the first quadrilateral, parallel to Ow 1, and through b, where ab intersects the (green) line the center of gravity of the second quadrilateral, draw bc parallel to Finally draw cL parallel to Ow 3. Where this line intersects MO be the point through which the (heavy red) line, passing through the ravity of the buttress taken as a whole, should be drawn. The distance

X_0, measured from IK, should then be 2.25 ft or very nearly this, allowi slight errors of drawing, and the same as that found by MOMENTS. Fig. 5 the same method of determining th tion of the center of gravity of a b similar to the one illustrated in Fig

After this line is found, the m of determining the stability of th is the same as that given for the p Fig. 2 and Fig. 4. If the butt more than one foot thick, that right-angles to the plane of the pa cubic contents must be determi order to find its weight. It is however, to divide the total thr the thickness of the buttress. Thi the thrust per foot of thickness buttress.

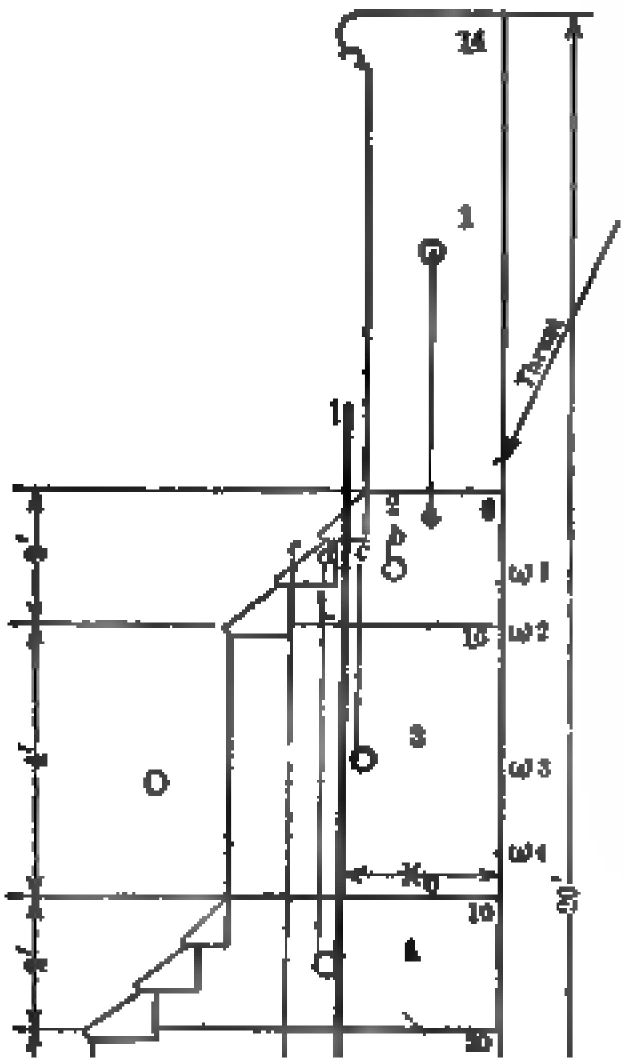

Fig. 5. Center of Gravity of Wall and Buttress

The Line of Pressure or L Resistance.* The LINE OF RESI or the LINE OF PRESSURE of a p buttress is a line drawn throu CENTER OF PRESSURE of each joint. The CENTER OF PRESSURE of any joint is the point in which the resultant of the forces acting on that portion of the pier above the joint cuts it. The line of pressure, or of resistance, when drawn in a pier, shows how near the greatest stress on any joint comes to the edges of that joint. It can be drawn by the following method.

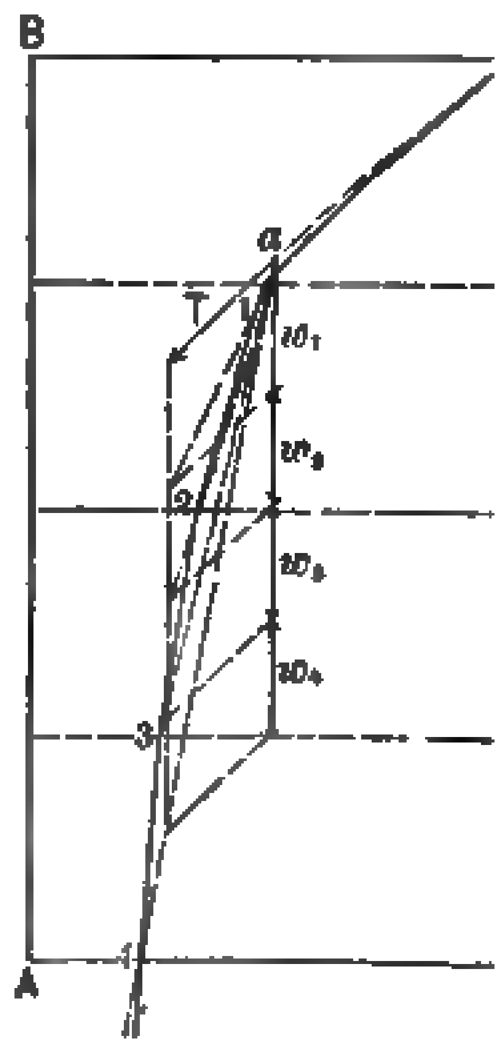

Fig. 6. Line of Pressure i

Let $ABCD$ (Fig. 6) be a pier whose LINE OF PRESSURE we wish to draw. Let T be the thrust against the pier divide the height of the pier into several parts, each 2 or 3 feet high, a by the horizontal dotted lines. It is more convenient to make the c

* This line is called, interchangeably, the line of pressure, the line of resist resistance-line, etc.

equal in height. Prolong the LINE OF THE THRUST, and draw a vertical through the center of gravity of the pier, intersecting the line of thrust at point *a*. From *a* lay off to a scale the thrust *T*, and the weights of the different parts of the pier, commencing with the weight of the upper portion. w_1 represents the weight of the portion above the first joint; w_2 represents the weight of the second part; and so on. The sum of the *w*'s will represent the weight of the whole pier.

Draw a parallelogram, with *T* and w_1 for its two sides. Draw the diagonal and produce it beyond the parallelogram, if necessary. Its point of intersection with the first joint will be a point in the line of pressure. Draw a second parallelogram, with *T* and $w_1 + w_2$ for its two sides. Draw the diagonal intersecting the second joint at the point 2. Continue in this way with the rest of the partial weights, the last diagonal intersecting the base *AD*, in the point 4. Join the points 1, 2, 3 and 4. The resulting broken line *C*1234 is the LINE OF PRESSURE or LINE OF RESISTANCE.

We have taken the simplest case as an example; but the same principles are true for any case. If the line of pressure of the pier at any point falls at a distance from the outside edge of the joint less than ONE-THIRD THE WIDTH OF THE JOINT, the pier is generally considered unsafe.

The Stability of a Wall and Buttress. By Moments and Graphical Method. The following example illustrates the application of these principles.

Example 2. Let Fig. 7 represent the section of a side wall of a church, with a buttress against it. Opposite the buttress, on the

Fig. 8. Stability of Wall and Buttress

a hammer-beam truss, which we will suppose exerts an wall of the church, amounting to about 9 600 lb. We at the resultant of the thrust acts at *P*, and at an angle tal. The dimensions of the wall and buttress are given ss is 2 ft thick, at right-angles with the plane of the ss the proper SIZE and FORM to enable the wall to resist

cide is whether or not the LINE OF PRESSURE cuts the ance in from *C* To ascertain this we must determine er of gravity of the wall and buttress above the joint *CD* determine this is by the METHOD OF MOMENTS, the s being taken about the line *KM* as an axis, or line of ready explained. The distance X_1 is, of course, half the r 1 ft. We next find the center of gravity of the part

CEFG (Fig. 8) by the method of diagonals; and scaling the distance X_2, ‑ it to be 2.95 ft.

The area $CEFG = A_2 =$ 10 sq ft; and the area $GIKL = A_1 =$ 26 sq ft $A =$ the total area above *CL*.

Then we have

$X_1 = 1$ ft	$A_1 = 26$ sq ft	$A_1 \times X_1 = 26$ sq ft × ft
$X_2 = 2.95$ ft	$A_2 = 10$ sq ft	$A_2 \times X_2 = 29.5$ sq ft × ft
	$A = 36$ sq ft	36)55.5 sq ft × ft
		$X_0 = 1.5$ ft

Expressed in EQUATIONS OF MOMENTS OF AREAS, this may be written as ‑ A representing the total area above the line *CL* (Fig. 8):

$$A \times X_0 = (A_1 \times X_1) + (A_2 \times X_2)$$

Hence,

$$X_0 = \frac{(A_1 \times X_1) + (A_2 \times X_2)}{A}$$

The center of gravity is at a distance 1.5 ft from the line *ED* (Fig. Fig. 7 measure the distance $X_0 = 1.5$ ft, and through the point *a* draw a line intersecting the line of the thrust prolonged at *O*. If the thrust is g for example, for a buttress 2 ft thick, it will be half that, or 4 800 l buttress 1 ft thick. We will call the weight of the masonry of which the l and wall is built, 150 lb per cu ft. Then the thrust is equivalent to 4 800/ cu ft of masonry. Laying this off to a scale from *O*, in the directio thrust, and the area of the masonry, 36 sq ft, from *O* on the vertical li pleting the rectangle, and drawing the diagonal, we find that the diago the joint *CD* at *t*, within the limits of safety. We must next find wl LINE OF PRESSURE cuts the base *AB*.

First, determine the position of the center of gravity of the whol This is determined by finding, as explained for the distances X_1 and X_2, tances X_2', X_3', in Fig. 8, and making the following computation, letti the total area above *AM*.

$X_1' = 1$ ft	$A_1' = 40$ sq ft	$A_1 \times X_1 = 40$ sq ft ×
$X_2' = 2.98$ ft	$A_2' = 24$ sq ft	$A_2 \times X_2 = 71.52$ sq ft ×
$X_3' = 4.95$ ft	$A_3' = 12$ sq ft	$A_3 \times X_3 = 59.40$ sq ft ×
	$A' = 76$ sq ft	76)170.92 sq ft ×
		$X_0' = 2.25$ ft

This, also, may be expressed in EQUATIONS OF MOMENTS OF AREAS, as e for the part above the line *CL*.

Then from the line *EB* (Fig. 7) lay off the distance $X_0' = 2.25$ ft, a through *d* a vertical line intersecting the line of the thrust at *O'*. On tical line, measure down from *O'* the whole area 76, to scale, as explaine and from the lower extremity of this line representing the area, lay o proper angle, the thrust $T = 32$. Draw the line *O'e*, intersecting the b This is the point where the LINE OF PRESSURE cuts the base; and, a a safe distance in from *A*, the buttress has sufficient stability. If th more offsets, we should proceed in the same way, finding where the PRESSURE cuts the joint at the top of each offset. The reason for doi

the LINE OF PRESSURE might cut the base at a safe distance from the edge, while higher up it might come outside of the buttress or too near outside face, thus making the buttress unstable. The method given in these ples is applicable to piers of any shape or material. If the LINE OF PRES- makes an angle of less than 30° with any horizontal joint, the stones the joint may SLIDE at this joint, or at least have a strong tendency to . SLIDING can be prevented either by doweling, or the joints. Such conditions, however, are in architectural construction.

Stability of a Wall and Buttress. Graphical od. This same example, which has been solved in foregoing case partly by MOMENTS and partly by ICAL METHODS, can be solved entirely by GRAPHICAL ODS. In this case it is not necessary to determine position of the line (the heavy red lines in Figs. 3 and sing through the center of gravity of the buttress as a whole. It is necessary, only, to determine (red) lines passing through the cen- of gravity of the various trapezoids rectangles into which it has been ided. To determine the position LINE OF PRESSURE and the various OF PRESSURE on the different , the method shown in Fig. 6 may ed. The construction shown in figure, in which the complete elograms of the forces acting at joint are drawn, may be simplified. If the parallelogram, only, or the ICLE OF THE FORCES acting at each , may be drawn and the whole uction placed at one side of the and afterwards transferred to the itself by means of parallel lines. the joint-planes *FG*, *EJ*, *CK* and calculate the areas of the parts of the wall and buttress, as *IKGF*, *FGJE*, *EJKC*, *CKNB* *NMA*, Fig. 9. These are respec- 14 sq ft, 6 sq ft, 16 sq ft, 10 sq ft sq ft. Lay off these areas to a of so many square units to a linear

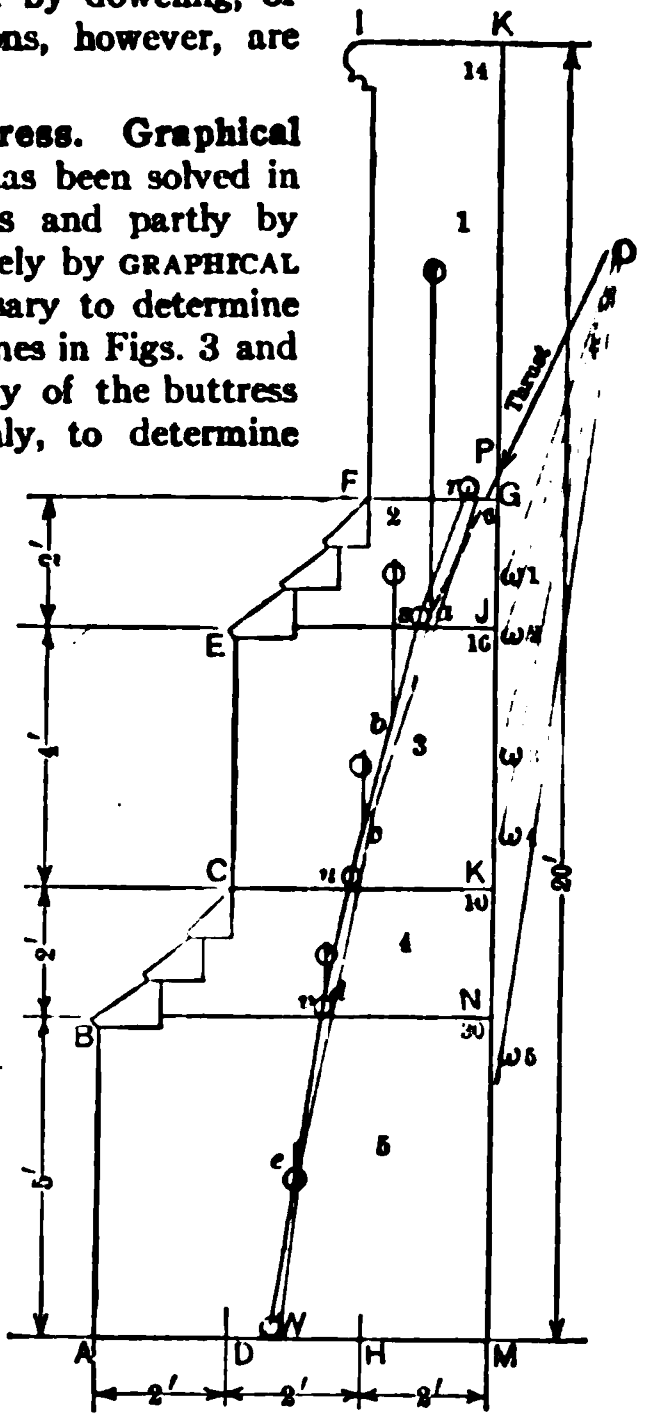

Fig. 9. Line of Pressure in Wall and Buttress

Pw 1, *w* 1 *w* 2, *w* 2 *w* 3, *w* 3 *w* 4 and *w* 4 *w* 5, along the line *KM*, begin- at the point of application of the THRUST. Lay off, at the same scale, the *OP* for one foot of thickness of the wall, and let this thrust be 4 800 lb. *Ow* 1, *Ow* 2, *Ow* 3, etc. Then *Ow* 1 will be the resultant of the thrust weight of the buttress above the joint *FG*, *Ow* 2 will be the resultant of resultant and the weight of that part of the buttress between the joints *EJ*, and so on until *Ow* 5 is reached, which is the resultant of the total of the buttress and the thrust as well as the resultant of the rectangle and the previous resultant. Prolong the thrust *OP*, until it cuts the) line through the center of gravity of the first rectangle *IKGF*, at *a*. his point draw a (green) line parallel to *Ow* 1 and prolong it backward

until it intersects the joint *FG* at the point within the small (red) circle. determines the CENTER OF PRESSURE on this joint. Next, draw *ab* (g parallel to *Ow* 2 and prolong it backward until it intersects the joint *EJ*, a CENTER OF PRESSURE on that joint. Repeat this operation to obtain CENTERS OF PRESSURE on each successive joint, drawing *bc*, *cd* and *de* pa respectively to *Ow* 3, *Ow* 4 and *Ow* 5.

It must be remembered, however, that *cd* does not have to be prolonged ward, as it cuts the joint *CK* below and to the left of the line passing thr the center of gravity of *EJKC*. Finally, join the various CENTERS OF PRES by the (red) broken line, which is the LINE OF PRESSURE in the buttress. this line lies within the MIDDLE THIRD of the construction, and the resulta the pressures on the various joint-planes do not make with the normals t joint-planes angles greater than the ANGLE OF FRICTION, the condition stability may be considered to be satisfied.

CHAPTER VIII

THE STABILITY OF MASONRY ARCHES *

By

GRENVILLE TEMPLE SNELLING

LATE MEMBER OF AMERICAN INSTITUTE OF ARCHITECTS

1. Arches

The Lintel and the Arch. When an opening is made in a masonry wall it is necessary to provide some means of spanning such opening to support the superimposed masonry. Two methods have been employed by constructors for this purpose. The first involves the use of the BEAM, GIRDER, CAP, or LINTEL, and the second the throwing of an ARCH from one side of the opening to the other. LINTELS are made of various materials, as wood, stone, reinforced concrete, cast iron and steel, and have cross-sections of different shapes. They are placed across the tops of the openings and transfer laterally the loads above, causing VERTICAL REACTIONS, only, in the side supports. An ARCH, on the contrary, is a particular arrangement of blocks of stone or other material, put together, generally along a curved line, in such a way that they resist the load by a balancing of certain THRUSTS and COUNTERTHRUSTS. An arch exerts on its supports an OUTWARD THRUST as well as a VERTICAL PRESSURE; and it is this outward thrust which requires that the arch should be used with caution when the abutments are not amply large and strong. The mechanical principles involved in the spanning of an opening by a lintel are much simpler than those of the arch and, historically, the lintel very considerably antedates the arch.

Definitions. Before taking up the principles of the arch, we will define the principal terms relating to it. The distance *ec* (Fig. 1) is called the SPAN of the arch; *ai*, the rise; *b*, the CROWN; the lower boundary *eac*, the SOFFIT or INTRADOS; the outer boundary *bb*, the BACK or EXTRADOS. The terms SOFFIT and BACK are also applied to the entire lower and upper curved surfaces of the whole arch. The sides of the arch which are seen are called the FACES. The blocks of which the arch itself is composed are called VOUSSOIRS; the center one, *K*, is called the KEYSTONE; and the lowest ones, *SS*, the SPRINGERS. In SEGMENTAL arches, or those of which the intrados is not a complete semicircle, the springers generally rest upon two stones, as *RR*, which have their upper surfaces cut to receive them; these stones are called SKEWBACKS. The line connecting the lower edges of the springers is called the SPRINGING-LINE; the sides of the arch are called the HAUNCHES; and the loads in the triangular spaces, between the haunches and a horizontal line drawn from the crown, are called the SPANDRELS. The blocks of masonry, or other material, which support two successive arches, are called PIERS; and the extreme blocks which, in the case of stone bridges, generally support, on one side, embankments of earth, are called ABUTMENTS. A pier strong enough to resist the thrust of one of two successive arches, in case the other one falls down, is some-

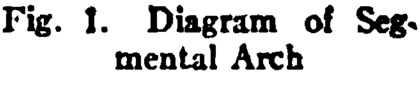

Fig. 1. Diagram of Segmental Arch

* See, also, Chapter XXXI.

times called an ABUTMENT-PIER. Besides their own weight, arches usuall port permanent loads or SURCHARGES of masonry or of earth.

Forms of Arches. In using arches in architectural construction FORMS of the arches are generally governed by the style of the building, a limited amount of space, rather than by engineering considerations. problem, therefore, that usually presents itself to the architect is not to the form and dimensions of an arch that will most economically and, fr engineering point of view, efficiently bear its load, but rather to determ an arch of a certain form and of certain dimensions will be stable an under its load. The SEMICIRCULAR and SEGMENTAL forms of arches a best as regards stability, and are the simplest to construct. ELLIPTICA THREE-CENTERED arches are not as strong as circular arches, and should be used where they can be given all the strength desirable.

The Strength of an Arch depends very much upon the care with whic built and upon the quality of the materials. In stone arches, special care s be taken to cut and lay the beds of stones accurately, and to make th joints thin and close, in order that the arches may be stressed as little as p in settling. To insure this, arches are sometimes built DRY, grout or mortar being afterwards run into the joints; but the advantage of this m is doubtful.

Brick Arches.* (See Figs. 2, 3, 4 and 5.) These may be built eit WEDGE-SHAPED bricks, molded or rubbed so as to fit to the radius of the

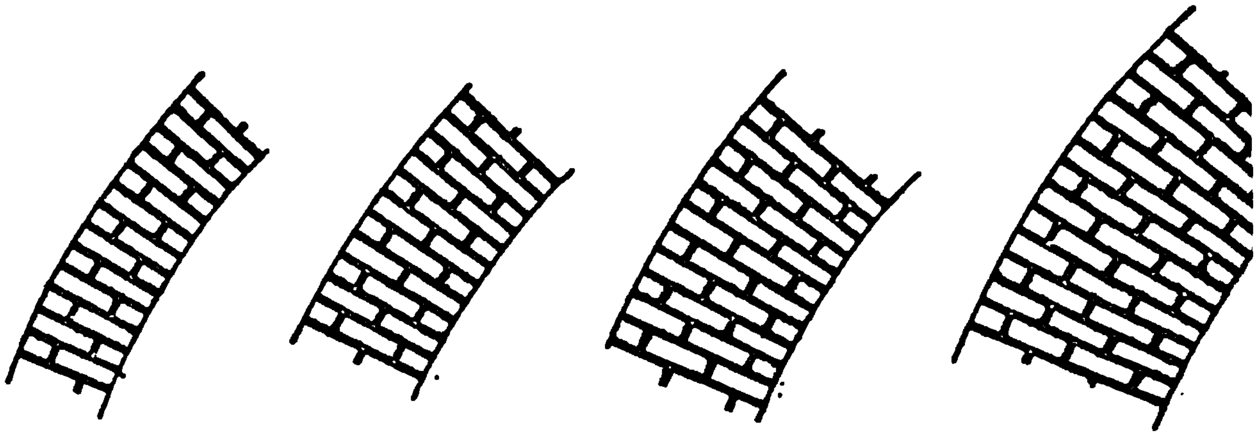

Fig. 2 Fig. 3 Fig. 4 Fig. 5
Brick Arches

or of bricks of COMMON SHAPE. The former method is undoubtedly the b it enables the bricks to be thoroughly bonded, as in a wall; but, as it in considerable expense to make the bricks of the proper shape, it is ver dom employed. When bricks of the ordinary shape are used, they a commodated to the curved figure of the arch by making the bed-joints th towards the intrados than they are at the extrados; or, if the curvature is s by driving thin pieces of slate into the outer edges of those joints; and dif methods are followed for BONDING them.

The usual method is to build the arch in concentric rings, each one-half thick; that is, to lay all the bricks as STRETCHERS and depend upon the t ity of the mortar for the connection of the several rings. Brick masonry structed in this way is deficient in strength, unless the bricks are laid in c mortar which is at least as tenacious as themselves. Another way is to i duce courses of HEADERS at intervals, and to connect pairs of half-brick

* For illustrations of the different methods of building brick arches, see Chapte Building Construction and Superintendence, Part I, Masons' Work, F. E. Kidder.

...ir. This may be done either by thickening with pieces of slate the ...of the outer ring of a pair of half-brick rings, so that there will be the ...number of courses of stretchers in each ring between two courses of ...ers; or by placing the courses of headers at such distances apart, that ...en each pair of them there will be one course of stretchers more in the ...than in the inner ring. The former method is best suited to arches of ...radius; the latter, to those of short radius. HOOP-IRON laid around the ...between half-brick rings, as well as longitudinally and radially, is very ...for strengthening brick arches. The bands of hoop-iron which traverse ...ch radially may also be bent, and prolonged into the bed-joints of the ...g and spandrels. By the aid of HOOP-IRON BOND, Sir Marc-Isambard ...el built a half-arch of bricks, laid in strong cement mortar, which stood, ...ting from its abutment like a bracket to the distance of 60 ft, until it was ...oyed by the undermining of its foundations.

...e only requirements in the New York City Building Laws for brick and ...arches is that "openings for doors and windows in all buildings shall have ...and sufficient arches of stone, brick, or terra-cotta, well built and keyed ...with good and sufficient abutments."

...e for the Radius of Brick Arches. A good RULE for the radius of ...ntal brick arches over windows, doors and other small openings is to ...e the RADIUS EQUAL TO THE ...H OF THE OPENING. This ...a good rise to the arch and ...sing proportion. In com... brickwork, when no par...r architectural effect is ...d, such as in the rowlock ...s thrown over the openings ...ilar walls, a RULE in very ...on use is to make the RISE ...e arch at the crown AN INCH ...IGHT FOR EVERY FOOT OF ...

...gmental Arches with Tie-... It is often desirable to ...openings in a wall by means ...ches when there are not a ...ient number of abutments ...thstand the thrusts. In ...of this kind each arch can be sprung from two cast-iron SKEWBACKS, held ...er by IRON RODS as is shown in Fig. 6. When this is done, it is necessary ...portion the size of the rods to the THRUST of the arch. The HORIZONTAL ...T of the arch may be very closely determined by the following formula:

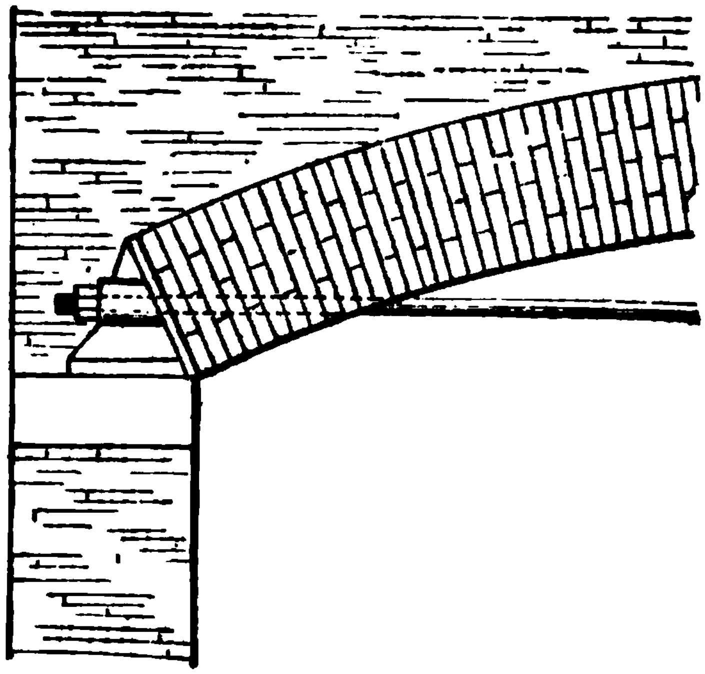

Fig. 6. Segmental Brick Arch, Cast-iron Skew-back and Wrought-iron Tie-rod

$$\text{Horizontal thrust} = \frac{\text{load on arch} \times \text{span}}{8 \times \text{rise of arch in feet}}$$

...he load is concentrated at the center of the arch, the thrust will be twice ...ven by this formula.

...TENSIONAL STRESS in the rod or rods will equal the HORIZONTAL THRUST ...arch and if there are two rods, the stress in each will be one-half the .... If there are three rods, then each must resist one-third the thrust. ...ng the stresses in the rods, the size of each may be determined from ...II, Chapter XI.

Example 1. Let us assume that a brick arch, like the one shown in] has a span of 15 ft, a rise at the center of 1 ft 6 in, and that it supports a brick wall. The weight of all the brick masonry above the arch does not upon it. Usually only an EQUILATERAL TRIANGLE of brickwork is consi the base of the triangle being the span. Assume, therefore, an equilater angle the sides of which are each 15 ft long. The altitude of this tria about 12.6 ft and its area will equal 15 ft × 12.6 ft × ½ = 94½ sq ft. If t is 12 in thick there will be 97½ cu ft of brickwork within this triangle wall; and since ordinary brickwork weighs about 115 lb per cu ft, its will be about 10 867 lb. Substituting these values in the formula,

$$\text{The horizontal thrust} = \frac{10\,867 \times 15}{8 \times 1.5} = 13\,584 \text{ lb}$$

Looking in Table II, page 388, it appears that one 1½-in or two 1⅛-in round, wrought-iron rods, or one 1⅛-in or two ¾-in round, upset, ste should be used.

Centers for Arches. A CENTER is a temporary structure, gener timber, on which the voussoirs of an arch are supported while the arch i built. It consists of parallel frames or ribs, placed at convenient di apart, curved on the outside to a line parallel to that of the soffit of th and supporting series of transverse planks, upon which the arch-stone The center commonly used is one which can be lowered, or STRUCK all piece, by driving out wedges from below it, so as to remove at once the s from every point of the arch. The center of an arch should not be struc the solid part of the backing has been built and the mortar has had t set and harden; and when an arch forms one of a series of arches wit between them, no center should be struck so as to leave a pier with a abutting against one side of it only, unless the pier has sufficient stability as an abutment. When possible, the STRIKING of the center of large brick should be delayed for two or three months after the arch is built, and the period that they are in place they should be EASED from time t This is done by EASING OUT the wedges under the centers a little at a as to let them down gradually and thus adjust any slight settling or shrin the masonry as it occurs.

Mechanical Principles of the Arch. In designing an arch, the firs tion to be settled is the FORM of the arch; and in regard to this, as already there is generally little choice. When the abutments are of ample size, MENTAL ARCH is the strongest; but when it is necessary to make the ab of the arch as small as possible, the SEMICIRCULAR or the POINTED ARCH be used.

Depth of Keystone. Having decided upon the form of the arch, the OF THE ARCH-RING must next be decided. This is generally determined puting the required DEPTH OF THE KEYSTONE and making the depth whole ring the same or a little larger. In considering the strength of a the depth of the keystone is considered to be only the distance from trados to the intrados of the arch; and if the keystone projects above t ring, as in Fig. 1, the projection is considered a part of the load on t There are several rules for determining the depth of the keystone, but empirical; and they differ so greatly that it is difficult to recommend a ticular one.

Rankine's Formula for Depth of Keystone. Professor Rankin is often quoted, and gives results which are probably true enough f

...is. It applies to both CIRCULAR and ELLIPTICAL ARCHES and is as follows. ...is a mean proportional between the inside radius at the crown, and 0.12 of ...t for a single arch, and 0.17 of a foot for an arch forming one of a series:

$$\text{Depth in feet of keystone for single arch} = \sqrt{(0.12 \times \text{radius at crown})}$$

$$\text{Depth in feet of keystone for arch of a series} = \sqrt{(0.17 \times \text{radius at crown})}$$

...e dimensions given by this formula seem to agree very well with those ...ally used in practice in arches of a certain kind. The formula, however, ...s the same depth of keystone for spans of any length, provided the radius ...e same; and in this particular it would seem that the rule is not satisfactory.

...rautwine's Formula for Depth of Keystone. Trautwine, from calcu...ns made for a large number of arches, deduced a formula for the depth of ...tone, which seems to agree with theory more closely than Rankine's formula. ...rule is, for CUT STONE,

$$\text{Depth of key in feet} = \left(\frac{\sqrt{\text{radius} + \text{half span}}}{4}\right) + 0.2 \text{ ft}$$

...or SECOND-CLASS work this depth may be increased about one-eighth part, ...r BRICKWORK OR FAIR RUBBLE, about one-third.

...ables for Depths of Keystones. Table I gives a few examples of the ...HS OF THE KEYSTONES of some bridges, together with the depths which ...ld be required by Trautwine's or Rankine's formula. From this table it ...ms that the results of both formulas agree very well with dimensions used ...tual practice.

Example 2. Having decided what the thickness of the arch-ring will remains to determine whether such an arch would be stable if built. following example will illustrate the method of determining this.

Consider an unloaded semicircular arch of 20-ft span.

First, to find the depth of the keystone, we will use Rankine's Formul

$$\text{Depth of key} = \sqrt{0.12 \times 10} = \sqrt{1.2} = 1.1 \text{ ft}$$

Trautwine's Formula gives nearly the same result,

$$\text{Depth of key} = \frac{\sqrt{10 + 10}}{4} + 0.2 \text{ ft} = 1.3 \text{ ft}$$

But if we should compute the stability of a 20-ft semicircular arch keystone 1.3 ft deep, we should find that the arch is very unstable; h this case, we cannot use the formula and must act upon our own jud In the opinion of the author, the arch-ring of such an arch should be 2½ ft deep and the stability of the arch should be tested for that th In all calculations on the arch, it is customary to consider it 1 ft t

* Taken from The Civil Engineer's Pocket-Book, John C. Trautwine.

...angles to its face. This allows the AREAS OF THE FACES to be substituted ...the ACTUAL WEIGHTS of the voussoirs and their loads. This method was ...d in the discussion of Retaining-Walls, Chapter IV, and Piers and But...ts, Chapter VII. Furthermore, it is evident that if an arch 1 ft thick is ...ble, any number of arches of the same dimensions built alongside of it would ...stable. In determining the stability of masonry arches it is also customary ...eglect any increase in the strength of the arch from the mortar in the joints, ...in other words, to consider the arch as laid up dry.

...aphic Determination of the Stability of Arches. An arch has already ...n defined as a particular arrangement of blocks of stone or other material, ...e blocks being called the vous...rs. For the sake of simplicity ...ider an UNLOADED ARCH. In ...h an arch each voussoir is sub...ted to the action of three forces, ...) the thrust that it receives from ...e voussoir next above it in the ...h-ring, (2) the force of gravitation, ...ts own weight and (3) the reaction ...the resultant thrust. The first two ...es combine into one and form ...thrust that this voussoir exerts on the one next below it in the arch-ring ...g. 7). The points in which these various thrusts cut the joints are called the ...ERS OF PRESSURE of the joints, while the line joining these centers of pres...e is called the LINE OF PRESSURE or LINE OF RESISTANCE.* In order that an ...h may be absolutely stable, this line of resistance must fall within the MIDDLE ...D of the arch-ring. (See Theorem of the Middle Third, Chapter IV) If ...arch is stable the centers of pressure on the various joint-lines are within ...middle third of the voussoir-depths and the angles made by the different ...sts with the normals to the joints are less than the ANGLE OF FRICTION of ...material of which the arch is constructed. If these conditions are not ful-

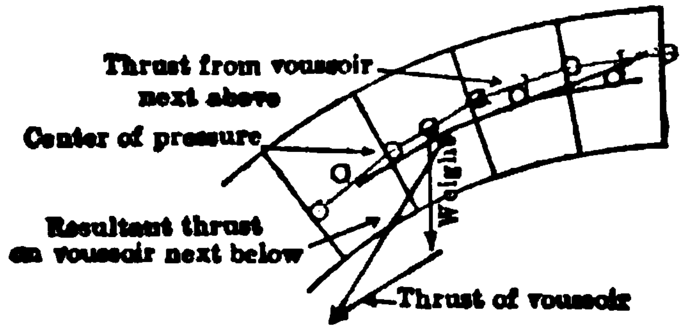

Fig. 7. Equilibrium of Forces on Voussoir

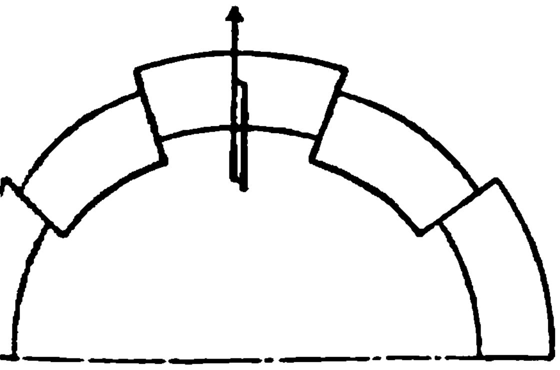

...8. Failure of Semicircular Arch. Haunches Sliding Down

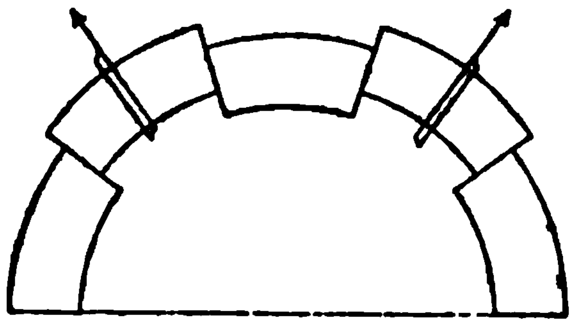

Fig. 9. Failure of Semicircular Arch. Haunches Sliding Up

...the CRITERIA OF SAFETY, explained in Chapter VII in the discussion of ...stability of a Buttress, will not be satisfied; and at any joint where these ...tions do not obtain, the voussoir above the joint will tend to SLIDE along ...joint-plane if the angle made by the thrust with a normal to the joint is ...r than the angle of friction. If the center of pressure lies outside the ...e third, there will be a tendency for the voussoir to OVERTURN. When ...tendencies reach extreme limits actual FAILURE may occur. Figures 8, 9, ...d 11 illustrate some of the ways in which an arch may fail, Figs. 8 and 9,

...is line is called, interchangeably, the LINE OF PRESSURE, the LINE OF RESISTANCE, ...RESISTANCE-LINE, etc. (See, also, Chapter XXXI, pages 1225 and 1234.)

showing different parts of the masonry sliding on the joints and Figs. 10
11 the failures caused by the passing of the line of pressure near the intrad
extrados.

Before passing to the actual discussion of the GRAPHIC METHOD for determ
the stability of arches, a consideration of the action of the STRESSES deve
in a construction of this kind will assist in a clearer understanding of the su

Fig. 8 shows how, if the line of resistance along the HAUNCHES of the
should turn sharply downward and in so doing make with a normal to o
the joints an angle greater than the angle of friction, the voussoirs at this

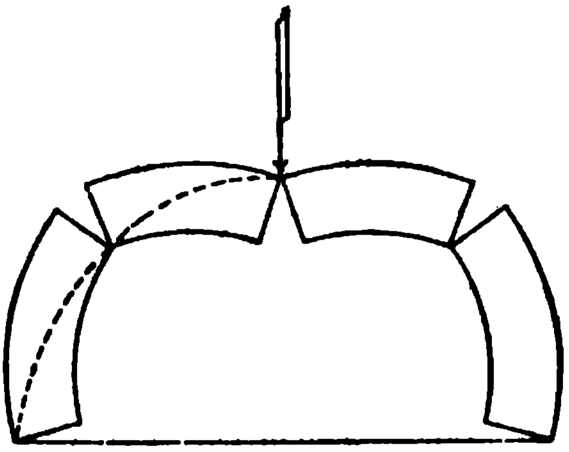

Fig. 10. Failure of Semicircular Arch. Opening of Arch-ring

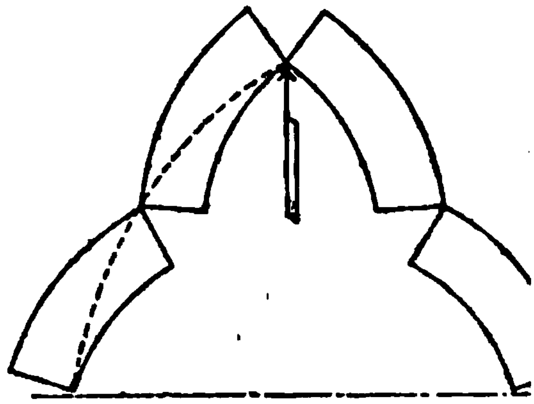

Fig. 11. Failure of Pointed A Opening of Arch-ring

would tend to slide inward on their joint-planes, forcing outward the vo
at the spring and crown of the arch. Fig. 9 shows how failure of the arch
occur under similar conditions, but with the line of resistance turning s
upward instead of downward. In these two cases it is conceivable th
though the RESISTANT THRUST at the joint where failure takes place mal
angle with the normal greater than the angle of friction, its point of appli
is still within the middle third of the joint.

Figs. 10 and 11, on the contrary, illustrate methods of failure in whi
though the angle made by the thrust may be such as to cause no SLIPPING
joint on another, its point of application is sufficiently outside the middl
of the arch-ring itself at the crown to cause OVERTURNING. In Fig. 10 t
of resistance passes high up, or perhaps entirely outside of the arch-ring,
voussoirs at the CROWN of the arch and low down along the HAUNCHE
Fig. 11 exactly contrary conditions exist.

The ten ways in which a masonry arch may fail have been classified as fol
"(1) By CRUSHING of the masonry; (2) By SLIDING of one voussoir upon a
(3) By one voussoir or section of masonry OVERTURNING about an a
voussoir or section; (4) By SHEARING in a horizontal or vertical plan
applying to solid concrete arches and not to voussoirs; (5) AS A COLUMN
the ratio of the unsupported length of an arch to its least width is great
twelve; (6) From STRIKING THE CENTERING before the mortar is hard o
the arch, although stable under the full load, is not stable under its
alone; (7) By STRIKING THE CENTERING or loading the arch during co
tion unsymmetrically; (8) By SETTLEMENT of the foundations; (9) By s
upon the foundations; (10) By OVERTURNING about any point in the
abutment. Methods (8) and (9) are the most common ways of failur
methods of failure, however, must be guarded against in design."

While some of these ways of failure may seem other than those illu
in the foregoing figures, they may be perhaps more properly considered

* W. J. Douglas in American Civil Engineering Pocket-Book, page 625.

...ure than ways of failure; and all, with the exception of the first, ...bout a position of the line of resistance in the arch-ring which causes ...in one of the ways noted.

...regard to the method of failure (1), the conditions may be such that the ...ing, although symmetrical, is so excessive that although the line of resistance ...ins within the middle third, the total pressure on a joint is sufficient to ...sh the material of which the arch is constructed. Such conditions, how-...r, are not common.

...m the foregoing discussion it is evident that in order to determine whether ...t a given arch is stable, it is necessary to find the true line of resistance ...sponding to the conditions of loading, form and dimensions of that par-...lar arch. It is always possible, in every arch-ring, to pass one maximum ...one minimum line of resistance. The true line of resistance will lie ...where between these two. The method of procedure, therefore, is to pass ...atively, a line of resistance, either a maximum or a minimum one, and see ...t remains within the middle third. If it does not, as it may not be the true ...of resistance, it does not mean necessarily that the arch is not stable. The ...t step then, is to note where it departs farthest from the middle third, and ...ss a second line of resistance through the same point on the crown-joint ...the point on the line of the middle third where the original line departs ...est from the middle third. If this second line of resistance remains within ...middle third it is reasonable to assume that the arch is stable. In these ...ese operations it is only necessary to consider half the arch when the loading ...mmetrical, and this is usually the case in architectural problems. The ...er of voussoirs, also, into which we divide the half-arch, is immaterial ...the joints need not coincide with those of the actual arch.

...order to pass a line of resistance through an arch-ring, the thrust exerted ...the other half at the crown-joint on the half-arch is first determined. ...thrust is then combined with the resultant of the weight of the first voussoir ...its load to determine the thrust exerted by this voussoir on the one next ...it, and this thrust, in turn, is combined in the same way with the resultant ...e weight and the load of the second voussoir, and so on down to the spring-...oint, for each succeeding voussoir. The points in which the various lines ...enting the thrusts cut the joints are known as the centers of pressure, ...the line joining them is the line of pressure or line of resistance. In ...rming this operation, the center of gravity of each voussoir as well as ...line passing through the center of gravity of the whole half-arch must be ...nd. The face of each voussoir may be considered a trapezoid, and any ...of the methods for finding the center of gravity of this figure may be used ...nding the center of gravity of each voussoir. The method of dividing the ...zoid into triangles is here employed and is shown at the side of the arch ...ig. 12. (See, also, in Chapters VI and VII.) As the determination ...e position of the line passing through the center of gravity of the half-arch ...e problem of finding the resultant of a system of parallel forces, the ...od involving the drawing of the equilibrium-polygon may be used. ...most convenient way to determine the stability of an arch is to use the ...ic method. The steps in this method are outlined in the preceding para-...h. Each of the operations will now be considered in detail.

...t Step. Draw one-half the arch to as large a scale as convenient, and ...e it into voussoirs of equal size. In the example shown in Fig. 12, the ...ing is divided into ten voussoirs of equal face-areas. As already pointed ...it is not necessary that these should represent the actual voussoirs of which ...ch is built. Next, the face-area of each of these voussoirs is to be found.

Where the arch-ring is divided into voussoirs of equal size, this is most
done by computing the total area of the arch-ring and dividing this total
by the number of voussoirs. The FORMULA for finding the area of one-ha
arch-ring is as follows:

$$\text{Area in square feet} = 0.7854\,(r^2 - r_1^2)$$

In this formula r is the outside radius and r_1 the inside radius in feet.
In this problem, for example, if the

$$\text{Area of the arch-ring} = 0\ 7854\,(12.5^2 - 10^2) = 44.2 \text{ sq ft}$$

as there are ten equal voussoirs, the area of each voussoir is 4.42 sq ft.
ing drawn out one-half of the arch-ring, divide the crown-joint into three parts, and with of $O'E$ and $O'F$ de the arcs dividin arch-ring into thi

Second Step. C the points E a through which t a MINIMUM LINE SISTANCE. The F and G, through a MAXIMUM LINE SISTANCE can be could equally we been chosen. It be noted that a loaded semicir arch is more apt by opening at t trados at the and at the extra the haunch, and fore, in this cas line of resistance ably passes nearer the OUTER THIRD at the CROWN and nearer the INNER at the HAUNCH. To determine this MINIMUM LINE OF RESISTANCE the MI THRUST, applied at the point E of the crown-joint, must first be determi

The half-arch is in equilibrium under the action of three forces: (THRUST AT THE CROWN, acting horizontally, applied at the point E and prev the half-arch from overturning inward; (2) the WEIGHT OF THE HAL considered as a vertical force, acting through its center of gravity and t to overturn it inwards about the point D; and (3) A FORCE EQUAL AND SITE TO THE RESULTANT of these two forces and passing from H to I. I intersection of the weight-line through the center of gravity of the hal with the line of action of the thrust at the crown, prolonged. It is thus p to construct the TRIANGLE OF THESE THREE FORCES and determine the magn of the thrusts, when the position of the weight-line of the half-arch is mined. It is first necessary to draw a vertical line through the center of g of each voussoir. The center of gravity of one of the voussoirs may be by the METHOD OF TRIANGLES, as shown in the supplementary figure at t of the arch-ring.

Having determined the positions of the centers of gravity of the vo

them on the voussoirs as shown. From the point E (Fig. 12) lay off vertically, to a scale of so many SQUARE UNITS TO A LINEAR UNIT, the area of each voussoir, one below the other, commencing with the top voussoir. The length of the line EK will then equal the total area of the arch-ring. From E and (Fig. 12) draw 45° lines intersecting at O. Draw Ow 1, Ow 2, Ow 3, etc. Then where OE intersects the first vertical line through the center of gravity of the first voussoir at a, draw a line parallel to Ow 1, intersecting the second vertical at b. Draw bc parallel to Ow 2, cd parallel to Ow 3 and so on to k. Draw kL parallel to Ow 10 and prolong it downward until it intersects EO prolonged, at L. A vertical line drawn through L will pass through the center of gravity of the half arch-ring. This is an application to a practical problem of the method of finding, by the EQUILIBRIUM-POLYGON, the line of action of the resultant of a SYSTEM OF PARALLEL FORCES. The weights of the individual voussoirs act along parallel vertical lines and the weight of the half-arch is their resultant in magnitude.

Third Step. To determine the THRUST AT THE CROWN and the REACTION AT THE SPRING, draw a horizontal line through E, the upper part of the middle third, and a vertical line through L, the two lines intersecting at I (Fig. 12). For the arch to be stable, it is, in general, considered necessary for the LINE OF RESISTANCE to pass within the MIDDLE THIRD. First, assume that the line of pressure or resistance starts at E and comes out at H. Draw a line IH the direction of the line of action of the resultant of the thrust at the crown and the weight of the half-arch, and draw, also, a horizontal line opposite the point w 10, between N and M. This horizontal line MN represents the magnitude of the horizontal thrust at the crown, for INM is the TRIANGLE OF THE THREE FORCES in equilibrium, the THRUST at the crown, the WEIGHT of the half-arch and the REACTION at the spring. Draw w 10 O^p parallel to HI, and the lines O^pw 1, O^pw 2, O^pw 3, etc. O^pE, equal to NM, is the thrust at the crown, and w 10 O^p, equal to MI, the reaction at the spring. INM and EKO^p are similar triangles.

Fourth Step. It is required next, to determine the LINE OF RESISTANCE through the arch-ring. The thrust at E is combined with the weight of the first voussoir; their resultant is found and in turn combined with the weight of the second voussoir; and so on for all the voussoirs. The intersections of these resultants with the joint-lines are the CENTERS OF PRESSURE; the line joining the centers of pressure is the LINE OF RESISTANCE.

These resultants could be determined by drawing a series of PARALLELOGRAMS OF FORCES over each voussoir. This would complicate the figure and involve unnecessary labor. It is found more convenient to draw the TRIANGLES OF FORCES one after the other, at the right-hand side of the figure and then transfer the results thus obtained by means of parallel lines to the figure itself, especially as the weights of the voussoirs have already been laid off along the line EK, at Ew 1, w 2, w 3, w 4, w 5, etc.

Then from the point where O^pE prolonged intersects the first vertical in voussoir number 1, draw a (green) line to the second vertical, parallel to O^pw_1; from this point, a (green) line to the third vertical, parallel to O^pw 2 and so on. The last line should pass through H. Join the various points, where these (green) lines cut the joints at the centers of pressure, by the broken (red) line. The last line drawn is the LINE OF RESISTANCE. If this line lies entirely within the MIDDLE THIRD of the arch-ring, the arch may be considered to be stable. Suppose that the line of resistance passes not only outside of the middle third but also outside of the arch-ring itself; it is still possible that the arch is unstable. This is the case in Fig. 12 and we will next determine if a

line of resistance can be drawn which will remain within the limits of the mid third of the arch-ring.

Fifth Step. The Second Trial. Reproducing the condition of Fig. 12 Fig. 13, without the construction lines, it is seen that the LINE OF RESISTA leaves the arch-ring at *R* enters it again at *S*, while furthest from it at *U*. If, at a perpendicular is erected straight line joining the points *R* and *S*, this per dicular line *VW*, called the I OF FRACTURE, will be appr mately the trace of the p along which, with the lin resistance under considera the arch will tend to fail, sumedly by TURNING OVE the right about the poin This shows that the THRUS THE CROWN, assumed to applied at the point *E*, wh sufficient intensity to main equilibrium about *H*, is n sufficient intensity to mai equilibrium about *V*. If a SECOND THRUST, of suff intensity to maintain equilibrium about *V*, or better, about *X*, can be ap at *E* without being so great in magnitude that it will OVERTURN THE OUTWARD about *G*, or some other point on the outer line of the middle thi

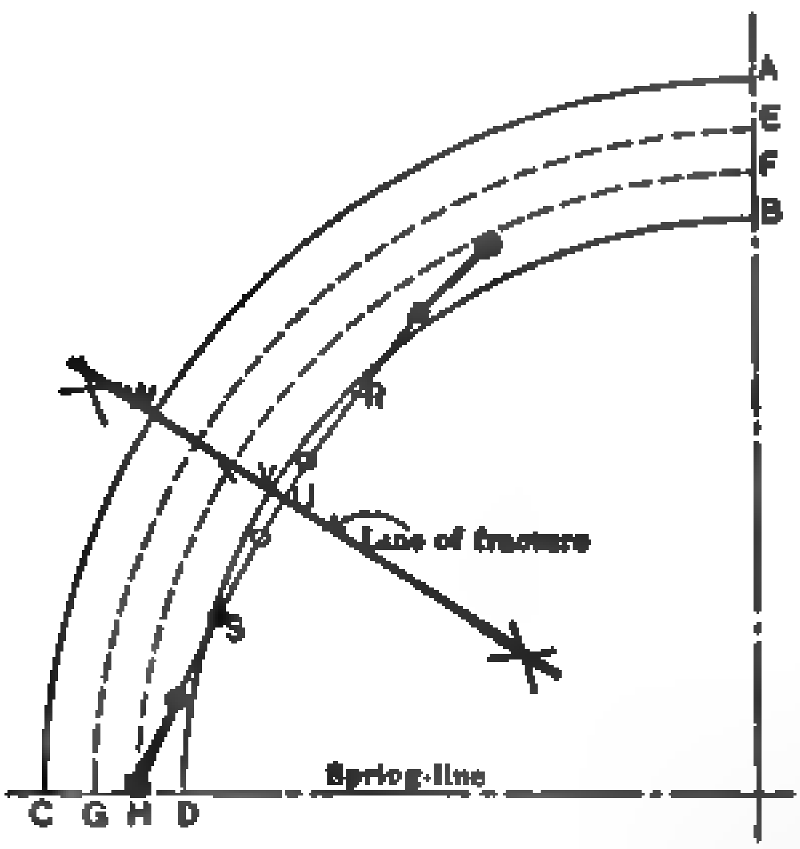

Fig. 13. Line of Fracture in Unloaded Semicircular Arch-ring

Fig. 14. Second Line of Pressure in Unloaded Semicircular Arch-ring

is reasonable to conclude that the line of resistance resulting from this t very nearly the TRUE LINE OF RESISTANCE in the arch-ring and that t is stable.

In order to determine this NEW LINE OF RESISTANCE the NEW THRUST

… must be found (Fig. 14). The preliminary steps required for this are … same as before until the seventh voussoir is reached. This is divided into … voussoirs by the line VW (Fig. 14), one being $w6\ w6^a$ and the other the … mainder of this seventh voussoir, and this division must be allowed for along … load-line EK, at $w6\ w6^a$. The line $w6\ w6^a$ represents the area of vous… 6^a, and the line $w6^a\ w7$ the area of the remainder of the seventh voussoir. The vertical line IL, passing through the center of gravity of that part of the … arch above the line VW, is found by prolonging backwards the line hg, … lel to $O\ w6^a$, until it intersects OE at L. To find the NEW THRUST AT THE … by completing the TRIANGLE OF FORCES for this thrust and the force … and opposite to their resultant, the inclined (blue) line must be drawn … gh the point X and the horizontal (blue) line through $w6^a$. The new thrust … is as before NM, equal to O^pE. This thrust is laid off at O^pE, the (green) … $O^pw\ 1$, $O^pw\ 2$, $O^pw\ 3$, etc., being drawn as before and the new line of re… … being drawn through the points where the parallels to these (green)

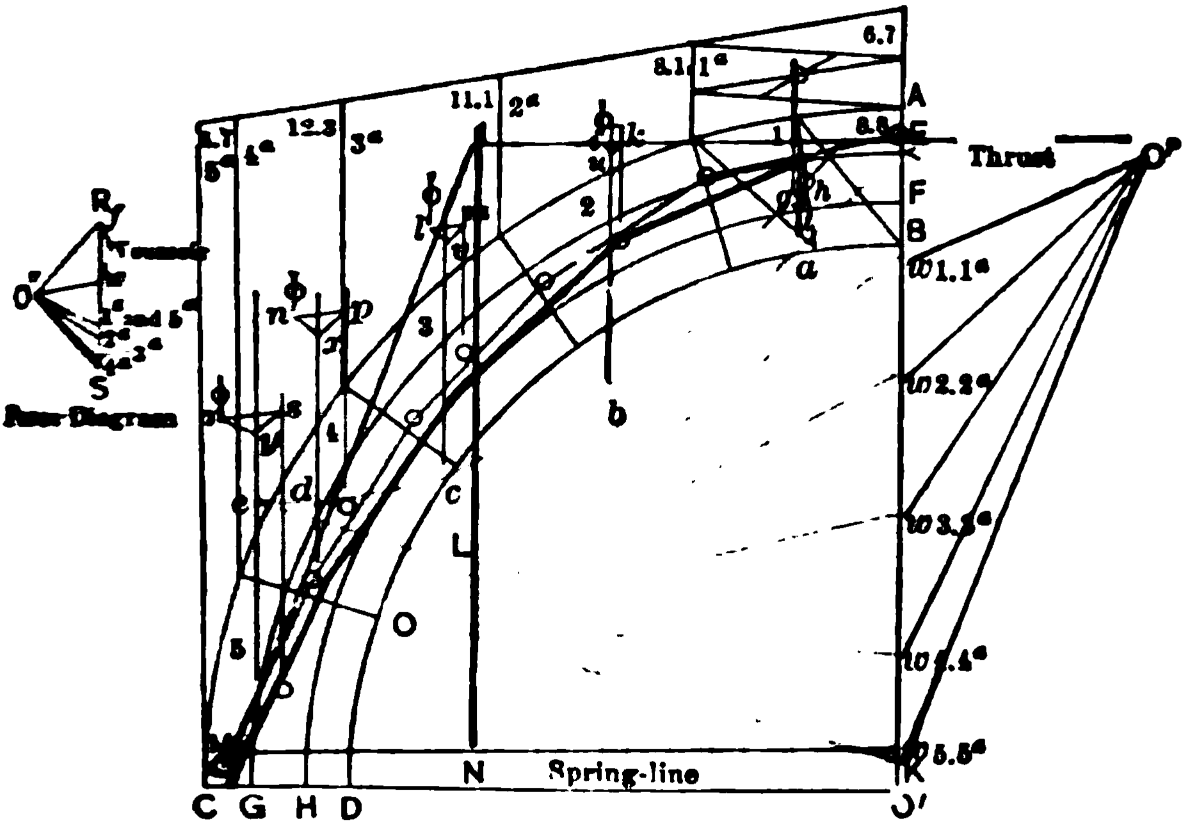

Fig. 15. Line of Pressure in Loaded Semicircular Arch-ring

… cut the joints. This NEW LINE OF RESISTANCE, if drawn correctly, should … through X. It lies within the middle third, except for a short distance at … springing, and hence it is justifiable to consider the arch stable. If it had … outside the middle third to any great extent, in this second trial, this … mption would not have been justified.

… is discussion explains the method of determining the stability of an UN… … SEMICIRCULAR ARCH. Such cases very seldom occur in practice, but … serve to illustrate the methods which apply generally to all other cases. … LOADED ARCH-RINGS there is slight difference in the method of determining … position of the center of gravity.

… mple 3. A LOADED OR SURCHARGED SEMICIRCULAR ARCH (Fig. 15) will be … dered next. Assume the same arch shown in Figs. 12, 13 and 14, and sup… … to be loaded with a wall of masonry of the same thickness and weight … are foot as that of the arch-ring, the upper surface of the wall being an … plane, 1 ft above the arch-ring at the crown, and 8 ft above it at the … The assumption of the particular load in this case is a purely arbitrary

one for the purpose of illustrating the method of solution. The determin of the ACTUAL LOAD that comes upon an arch in any given case is by no r easy, so numerous are the uncertain elements that affect the transmiss this load to the arch-ring.

The customary procedure is to assume that the load is itself transmitted arch-ring VERTICALLY DOWNWARD. Each voussoir thus receives that porti the load which is included between two vertical lines drawn to the poi intersection of the joints on either side of that voussoir with the extrados. ing made this assumption it is necessary next to determine how much total superimposed masonry bears upon the arch-ring.

It is a matter of common observation that if an opening is made in a especially in a wall that has stood for some time, the major portion of the ma above this opening is self-supporting, limited portions only, bounded by a what irregular line, falling down into the opening, as shown in Fig. 16.

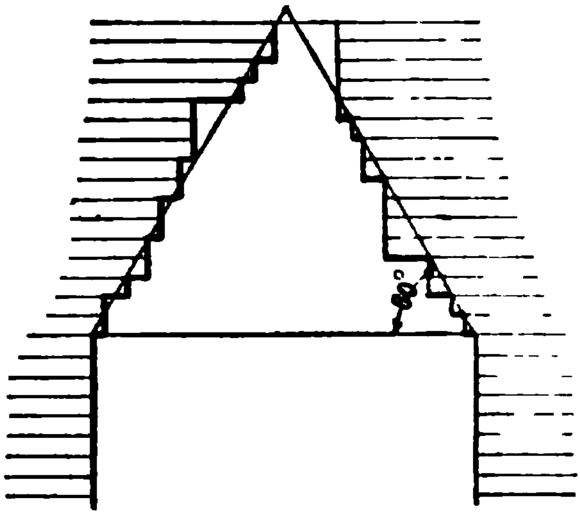

Fig. 16. Triangle of Loading over Opening

profile of this boundary-line depends the nature of the material of whic wall is constructed, the size of the s bricks, etc., the character of the and the quality of the mortar. being the case, all the masonry abo arch should not be considered a load on it. Some authorities recom considering as the proper load, for l work, a TRIANGULAR PART of the the sides of which triangle have a clination to the horizontal of 45°; assume an inclination of 60° (Fig. (See, also, Chapter XV, page 612.) exact determination of this loa mechanical laws is difficult if not impossible. It is better to consider case separately and by a careful study of the conditions to determine as c as possible just what portion of the weight of the superimposed maso transmitted to the arch. Having assumed a load for this particular arc (Fig. 15), the procedure is as follows:

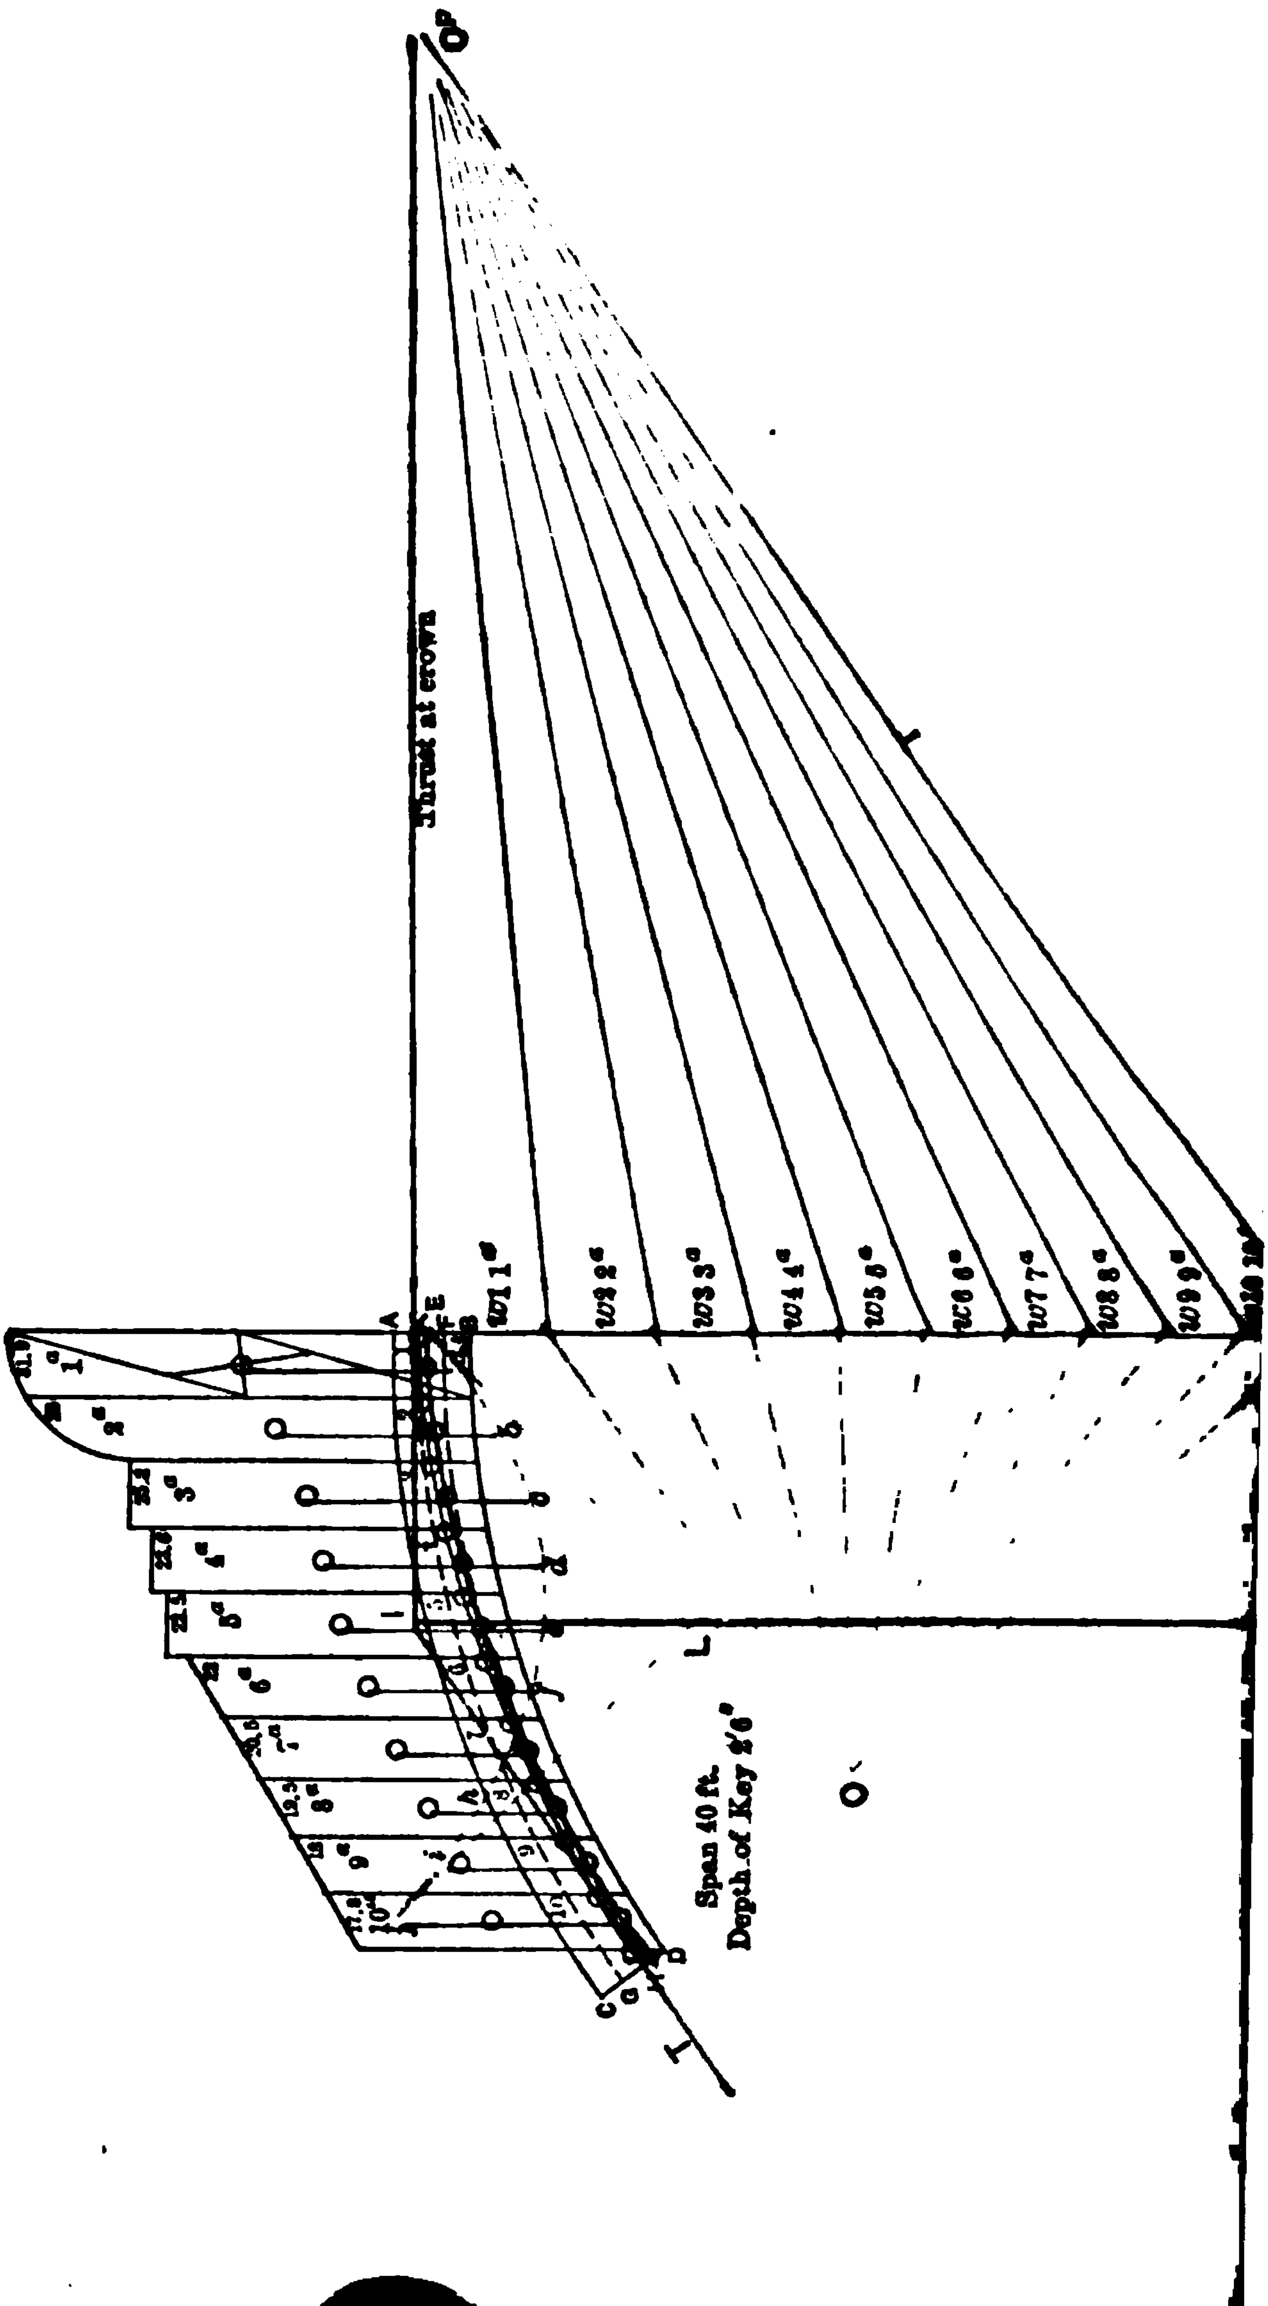
First Step of Example 3. This involves the finding of the CENTER OF GR of the ARCH-RING AND LOAD COMBINED. Divide the arch-ring into five vou of equal size. In this case the area of each voussoir is equal to 44.2 sq ft ÷ 8.8 sq ft. (See under First Step, Fig. 12, preceding example.) The surc or load, also, is divided into five parts, not necessarily equal, by drawin tical lines to the points of intersection of the joints and the extrados. Th proximate area of each one of these surcharges is found by multiplyin the sum of the lengths of the two parallel vertical sides by the length horizontal distance between them.

The positions of the center of gravity of each voussoir and of the cen gravity of each voussoir-surcharge are determined as in the preceding exa The CENTERS OF GRAVITY of these SURCHARGES can be found by dividing TRAPEZOIDAL FIGURE into TRIANGLES as shown, remembering that the M LINE in this case joins the middle points of the two parallel faces. As the are vertical, the medial lines approach a horizontal direction. This con tion is shown on surcharge 1^a, Fig. 15. Having drawn the lines of act the weights of the various voussoirs and of their loads through their resp centers of gravity, the lines of action of the combined weight of each vo and its load must be found. The construction for this operation is sho

left of Fig. 15. The method used, that of the EQUILIBRIUM-POLYGON, the same as that employed in the previous example to find the line passing through the center of gravity of the half-arch, only in this case the forces are reduced to two. Furthermore, as the areas of the various voussoirs are equal it is possible to superimpose the different FORCE-DIAGRAMS, one over the other, and so save considerable labor. Begin, therefore, by laying off along the line at the left of the loaded arch, and at any convenient scale, fw, the area (weight) of a voussoir; then from w, in turn, the distances $w\ 1^a$, $w\ 2^a$, $w\ 3^a$, etc., representing the areas of the successive surcharges, 1^a, 2^a, 3^a, etc., always at the same scale. The scale to be employed later for laying off the combined weights of the voussoirs and their loads along the line AK is the best one to choose, but a difference in scales is not important. In this particular instance the two points 1^a and 5^a coincide because the two areas 1^a and 5^a, although of different shapes, are each equal to 6.7 sq ft. This is a mere coincidence. Next draw f and $4^a\ O''$ at 45° to RS, and in turn, $O''w$, $O''1^a$, $O''2^a$, etc. As the problem which presents itself is to combine the weight of each voussoir with its individual surcharge, and as the weights of all the voussoirs are equal, and, furthermore, the forces which are to be combined to find their resultant are only two, the POLE-LINES or RAYS $O''f$ and $O''w$ in the FORCE-DIAGRAM serve in each case, and the FUNICULAR POLYGON is reduced to a TRIANGLE. Draw gh, ik, lm, np and rn parallel to $O''w$, and ht, ku, mv, px and sy parallel to $O''f$; and draw gt, iu, lv, nx and ry parallel respectively to $O''1^a$, $O''2^a$, $O''3^a$, $O''4^a$ and $O''5^a$. The points t, u, v, x and y are the points through which to draw the heavy (red) lines of action of the combined weights of the voussoirs and their surcharges. Having found and drawn these lines, the procedure for finding the line IN is the same as in the previous example, except that the distances $Ew1\ 1^a$, $w1\ 1^a$, 2^a, etc., instead of being equal to the weights of the voussoirs alone, are equal to the combined weights of each voussoir and its surcharge, $Ew1\ 1^a$, being equal to $f\ 1^a$, $w1\ 1^a$ to $w2\ 2^a$ being equal to $f\ 2^a$, etc.

The line EO is drawn at 45° to AO', but as the position of the POLE-POINT, is entirely arbitrary, the line $Ow\ 5\ 5^a$ has been drawn in this case in such a way that O falls well over toward the left of the figure, thus avoiding a certain amount of confusion in the drawing which would have resulted if $Ow\ 5\ 5^a$ made an angle of 45° with AO'. The lines ab, bc, cd and de are drawn respectively parallel to $w1\ 1^aO$, $w2\ 2^aO$, etc., and eL is produced backward parallel to $5\ 5^a$ until it intersects EO at L, which is the point through which the heavy (red) line IN, passing through the center of gravity of the whole half-arch and its surcharge, should be drawn. A vertical line drawn through L will pass through the center of gravity of the arch-ring and its load. If this were an arch used for a building and if the only abutments possible were of such size and shape that it was essential for the thrust exerted by the last or fifth voussoir on the abutments to approach more nearly the vertical, the architectural expedient of increasing slightly the weight of the surcharge, 5^a, on this voussoir by adding a piece of ornament, such as a cartouche, could be resorted to. A case of this kind in actual practice is the archway over the entrance to the service-court of the Grand Opera House in Paris, where the pyramidal stone ornaments that surmount the cornice on either side of the central motive were added after the original design was made, with this end in view. In the example illustrated in Fig. 15 the areas of the faces of the surcharges are shown by the figures on the faces. For the second surcharge from the crown, for example, the area is ... sq ft.

Second Step of Example 3. This involves the determination of the THRUST at the CROWN and the LINE OF RESISTANCE. The method of finding this thrust



Thrust at crown
Span 40 ft.
Depth of Key 2'6"

the crown is similar to that employed in the previous example. In that example, however, it was found that this thrust, applied at E and determined assuming H as the point of application of the reaction at the spring, produced a line of resistance which fell considerably below the middle third. But instead of repeating the operations required by a second trial, as in the previous example, the expedient is tried of slightly increasing the inclination to the vertical of the (blue) line IM, and so assuming a somewhat greater THRUST AT THE CROWN. As the line of resistance, as shown in Fig. 15, passed with this thrust departs but slightly from the middle third near the springing, we are justified in assuming that this arch is stable under the given conditions. The method used for this example may be used, also, for a SEMIELLIPTICAL ARCH.

Example 4. This example (Fig. 17) illustrates the application of the preceding methods, with some variations, to the determination of the position of the center of gravity of a LOADED SEGMENTAL ARCH, the thrusts at the crown and springing and the line of pressure or resistance through the arch-ring. In this case, instead of dividing the arch-ring into a certain number of voussoirs with joints radiating from a center and considering the surcharge on each individual voussoir, the method of dividing the arch-ring and its load into VERTICAL SLICES, in this case two feet wide, and computing the areas of the entire slices has been adopted. Having computed the areas of the slices, including in each case the combined area of the sliced part of the arch-ring and its surcharge, we lay them off in order on E, to a convenient scale, and then proceed as in the previous examples. The remaining steps required to determine the thrusts at the crown and at the springing and the line of resistance are also the same as explained in the foregoing paragraphs. In a FLAT SEGMENTAL ARCH there is practically no need of dividing the arch-ring into voussoirs by JOINTS RADIATING FROM A CENTER, in order to determine its stability. Of course, when built, they must be made to radiate. Fig. 17 shows the GRAPHICAL ANALYSIS of an arch of 40-ft span and carrying a load $13\frac{1}{2}$ ft high at the crown. The depth of the arch-ring is 2 ft 6 in. It is seen that the line of resistance lies entirely within the middle third, and that the arch is therefore stable. It is to be noted that the line of resistance in a SEGMENTAL ARCH should be drawn through the LOWER or INNER EDGE of the middle third at the springing. It is to be noted, also, that the horizontal thrust at the crown and the thrust T against the supports are very great when compared with those in a SEMICIRCULAR ARCH; and hence, although the SEGMENTAL arch is the stronger of the two, it requires much heavier abutments. The foregoing examples serve to show the various methods of determining the stability and thrusts of any arch used in buildings.

CHAPTER IX

REACTIONS AND BENDING MOMENTS FOR BE

By

CHARLES P. WARREN

LATE ASSISTANT PROFESSOR OF ARCHITECTURE, COLUMBIA UNIVERS

1. Reactions for Simple Beams

Definition of Reaction. One of the fundamental principles of static rium is that the sum of all the forces acting upon a body in one direction balanced by the sum of another set of forces acting in the opposite d Therefore, in the case of a beam or girder, the loads acting downward balanced by an equal set of forces at the supports, acting upward. T ward forces are called THRUSTS, or REACTIONS and in computing the of beams one of the first steps is to determine them, since the loads are given in intensity and position.

The Principle of Moments. The reactions may be determined application of another fundamental principle of static equilibrium fo acting in the same plane. The algebraic sum of the moments of all th

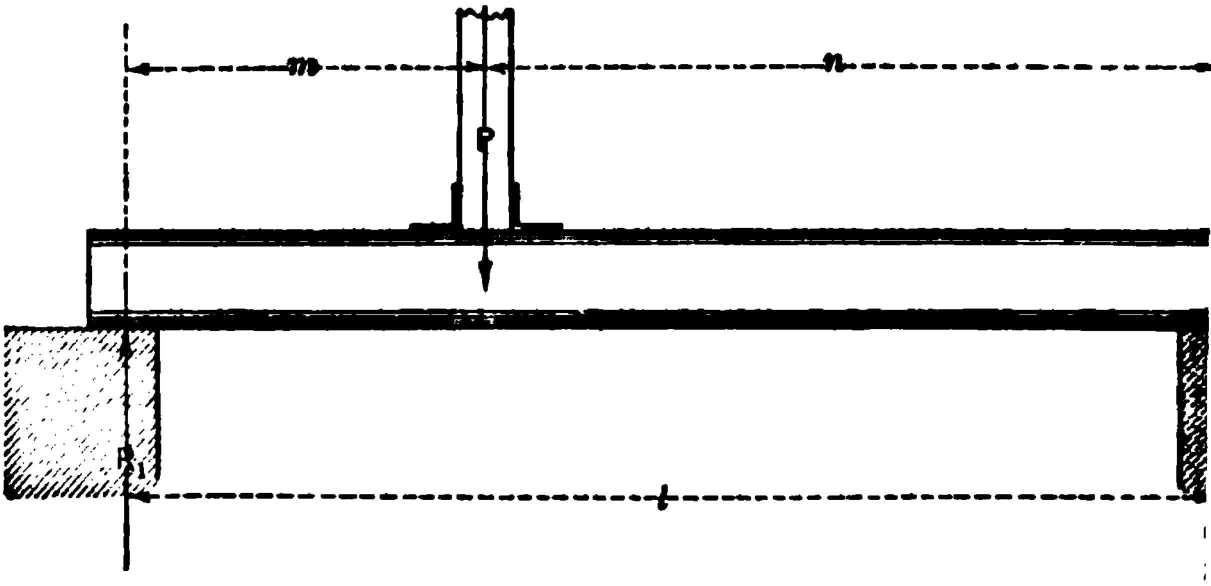


Fig. 1. Simple Beam. One Concentrated Load

taken about any point in the plane in which they act must be zero. The OF A FORCE about a point is the product of the magnitude or intensity of by the perpendicular distance between the LINE OF ACTION of the force point. The perpendicular distance is called the LEVER-ARM, and the CENTER OF MOMENTS. Forces acting upward are considered POS those acting downward are considered NEGATIVE. The center of mom be taken at any point in the plane of action of the forces, but it convenient to take it at one of the reactions. For example, the beam supports a concentrated load P at the distance m from the left support. the left reaction take the center of moments at the right reaction. EQUATION OF MOMENTS is

$$R_1l - Pn = 0.$$

from which $$R_1 = Pn/l$$

In like manner, to find R_2 the center of moments is taken at R_1 and the equation of moments is

$$R_2l - Pm = 0, \text{ from which } R_2 = Pm/l \qquad (1)'$$

From the first principle of statics mentioned, $R_1 + R_2$ must equal P; hence, as a check, $(Pn/l) + (Pm/l) = P$.

Example 1. Let a beam 15 ft in span support a concentrated load of 700 lb, 6 ft from the left end; or, $P = 700$, $m = 6$ and $n = 9$. Then, from Formula (1). $R_1 = (700 \times 9)/15 = 420$ lb. $R_2 = (700 \times 6)/15 = 280$ lb, and $420 + 280 = 700$ lb. For a concentrated load at the middle, or for a uniform load over a simple beam, it is evident without applying the conditions of equilibrium, that each reaction is one-half the load, for, in Formulas (1) and (1)′, m and n each equal $\frac{1}{2}l$ and R_1 and $R_2 = \frac{1}{2} P$.

For any number of concentrated loads (Fig. 2) the reactions may be found by adding together the reactions found by Formula (1) due to each load separately, or they may be computed in one operation by the following formula:

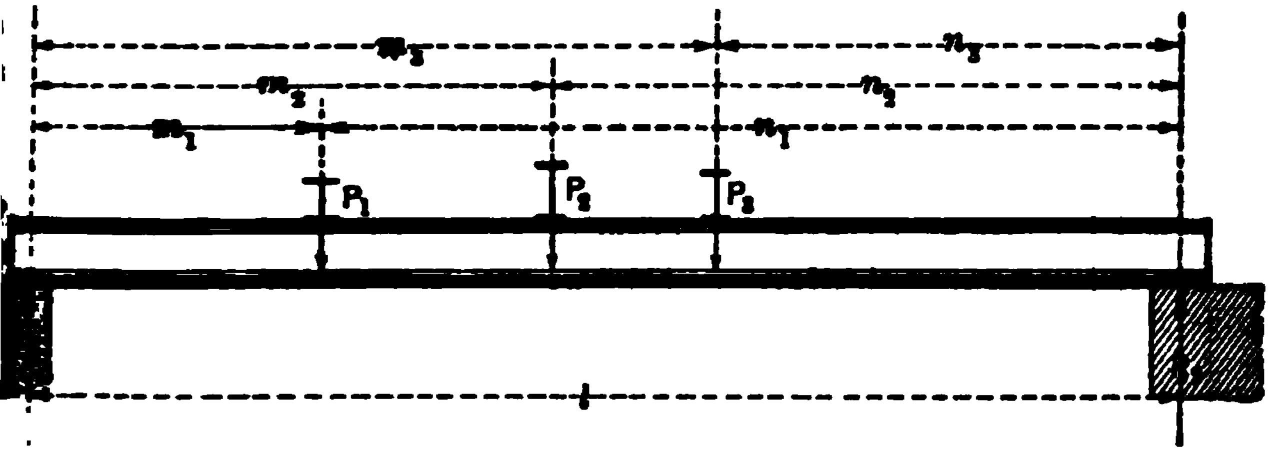

Fig. 2. Simple Beam. Three Concentrated Loads

To find the right reaction, the center of moments is taken at the left support, and the equation of moments is

$$R_2l - P_1m_1 - P_2m_2 - P_3m_3 = 0$$

hence,

$$R_2 = \frac{P_1m_1 + P_2m_2 + P_3m_3}{l} \qquad (2)$$

In like manner, to find R_1 the center of moments is taken at R_2 and the equation of moments is

$$R_1l - P_1n_1 - P_2n_2 - P_3n_3 = 0$$

from which

$$R_1 = \frac{P_1n_1 + P_2n_2 + P_3n_3}{l} \qquad (3)$$

Example 2. Suppose the beam in Fig. 2 is 20 ft in length. Let there be three concentrated loads of 500, 800 and 600 lb placed 5, 9 and 12 ft respectively from the left support. Then $l = 20$, $m_1 = 5$, $m_2 = 9$, $m_3 = 12$, $P_1 = 500$, $P_2 = 800$ and $P_3 = 600$. Substituting in Formulas (2) and (3),

$$R_2 = \frac{500 \times 5 + 800 \times 9 + 600 \times 12}{20} = 845 \text{ lb}$$

$$R_1 = \frac{500 \times 15 + 800 \times 11 + 600 \times 8}{20} = 1\,055 \text{ lb}$$

$$500 + 800 + 600 = 845 + 1\,055 = 1\,900 \text{ lb}$$

To find the reactions for a combination of uniformly distributed and centrated loads, to each of the reactions obtained by Formulas (1) or (2) f concentrated loads, add one-half the distributed load. Thus, suppos 20-ft beam in this example weighs 40 lb per linear ft. This is considere uniformly distributed load and for the entire beam it is 40 lb × 20 = 8 By the rule, one-half of this is added to each reaction, so that the total rea are, $R_2 = 845 + 400 = 1\,245$ lb and $R_1 = 1\,055 + 400 = 1\,455$ lb.

Example 3. For a distributed load applied over only a part of the span, Fig. 3, assume the load to be CONCENTRATED AT THE MIDDLE of the part

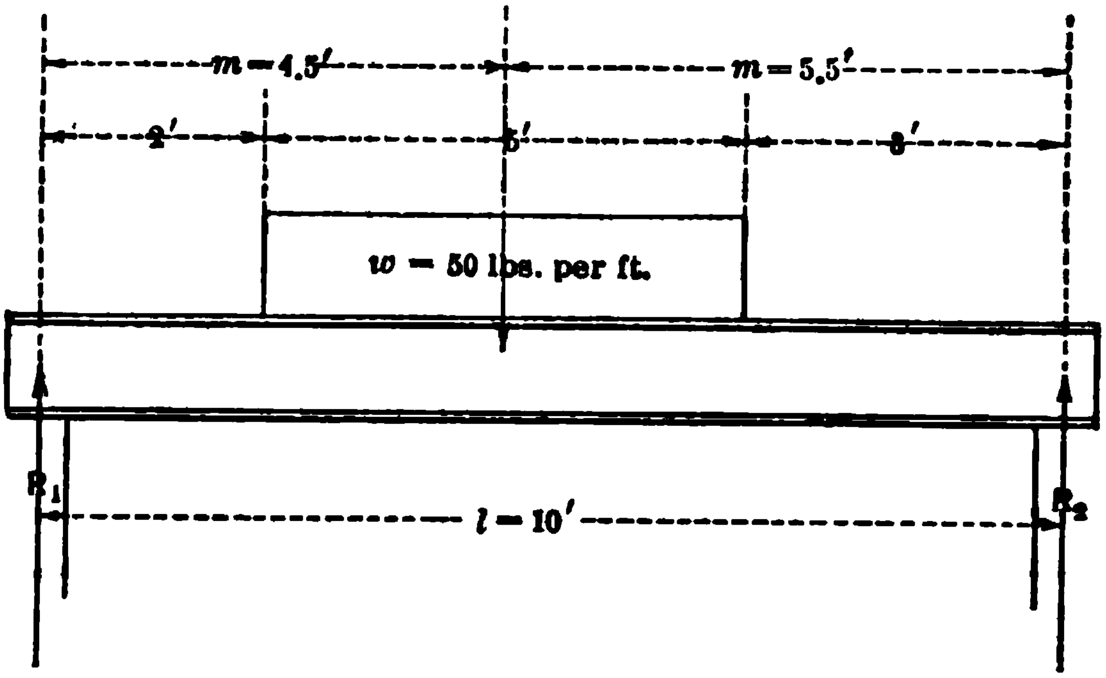

Fig. 3. Simple Beam. Distributed Load over Part of Span

which it acts and use Formulas (1) and (1)'. For example, let w (Fig. 3) eq lb per linear ft, applied for a distance of 5 ft over the beam. Then W, the load, is 50 lb × 5 = 250 lb. This may be assumed to be concentrated center, 4.5 ft from the left support. Then $P = 250$, $m = 4.5$ and $n = 5.5$ from Formulas (1) and (1)',

$$R_1 = \frac{250 \times 5.5}{10} = 137.5 \text{ lb}$$

and

$$R_2 = \frac{250 \times 4.5}{10} = 112.5 \text{ lb}$$

Therefore, for any combination of concentrated and uniform loads distri over the entire beam, or over only part of it, find the reactions due to the centrated loads by Formulas (1) or (2), and to them add the reactions due t uniformly distributed loads.

2. Bending Moments in Cantilever and Simple Beams*

Definitions. The bending moment is a measure of the tendencies of for break a beam by BENDING OR FLEXURE. Fig. 4 shows the manner in wh simple beam, supported at the ends, breaks when subjected to a load gr than it can bear. The effect of a load upon a beam is to cause it to SA BEND. The bending of the beam shortens, or compresses, the upper fiber stretches, or elongates, the lower fibers. So long as the resistance of the

* See, also, Chapter XV, pages 555 to 564.

shortening, or compression, and to stretching, or tension, is greater than the tendency of the load to disrupt them, the beam carries the load; but, when the load causes a greater tension, or compression, on the fibers than they are capable of resisting, the beam breaks. The stretching of the fibers before breaking allows the beam to bend; hence, the name BENDING MOMENT has been given to the forces causing a beam to BEND and perhaps ultimately to BREAK.

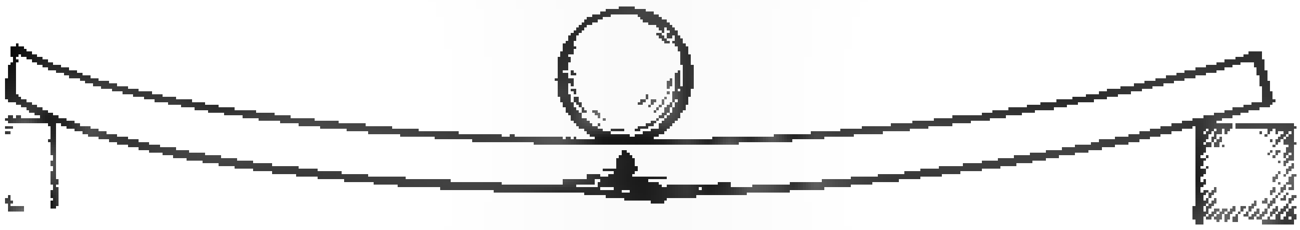

Fig. 4. Manner of Rupture of Simple Beam

In order to calculate the FLEXURAL STRENGTH OF A BEAM, it is necessary to ascertain the nature and extent, first, of the EXTERNAL FORCES acting to break the beam, and secondly of the INTERNAL FORCES OF STRESSES tending to resist rupture.* The external forces tending to break the beam by flexure are the DOWNWARD LOADS and the UPWARD REACTIONS. Each acts with a LEVERAGE equal to the perpendicular distance from its LINE OF ACTION to the section at which the beam tends to break. The algebraic sum of the moments of these external forces on the left, or right, of any section is called the BENDING MOMENT at that section, since it is the MOMENT OF THE RESULTANT OF THE FORCES which tends to bend the beam at that section. It is generally designated by M. Then, from the definition, the BENDING MOMENT for any section of a beam resting on two supports and in a state of flexure under a load or loads is M = the moment of either reaction minus the sum of the moments of the loads between that reaction and the section. The moment of the reaction is UPWARD, or POSITIVE, and the moment of any load DOWNWARD, or NEGATIVE, if the part of the beam on the left of the section is considered.

Bending Moments in Beams for Different Kinds of Loading

Case I

Beam Fixed at One End and Loaded with a Concentrated Load P, Near the Free End (Fig. 5).

Fig. 5. Cantilever Beam. Concentrated Load near Free End

Maximum bending moment, at wall $= P \times l$

Bending moment at any other section $x = Px$

Note. If l is in feet, the bending moment will be in foot-pounds; if l is in inches, the bending moment will be in inch-pounds.

Case II

Beam Fixed at One End and Loaded with a Uniformly Distributed Load W (Fig. 6)

Maximum bending moment, at wall $= W \times l/2$

At any other section x, $M = wx \times x/2 = wx^2/2$

Note. $W = wl$ and w = the load per unit of length.

* See Chapter X for a discussion of these internal stresses and of the resisting moment.

Case III

Beam Fixed at One End and Loaded with Both a Concentrated and a Uni Distributed Load (*Fig. 7*).

Maximum bending moment, at wall = $P \times l_2 + W \times l_1/2$

Fig. 6. Cantilever Beam. Uniformly Distributed Load

Fig. 7. Cantilever Beam. Distr uted Load and Load at Free En

Case IV

Beam Supported at Both Ends and Loaded with a Concentrated Load Middle (Fig. 8).

Maximum bending moment, under the load = $Pl/4$

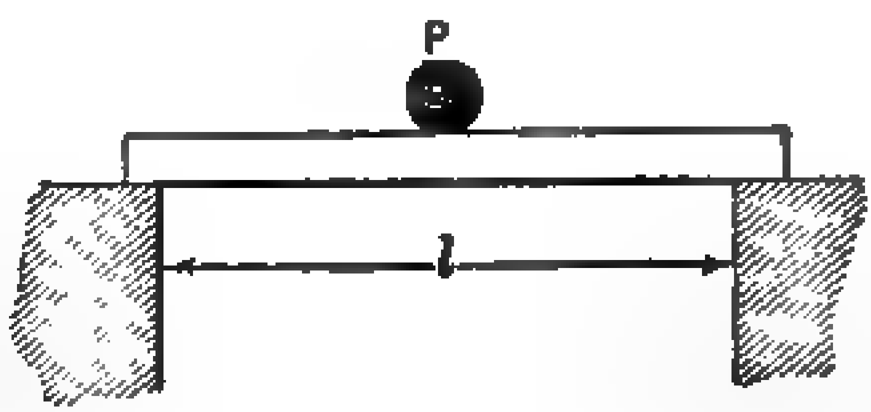

Fig. 8. Simple Beam. Concentrated Load at the Middle

Case V

Beam Supported at Both Ends and Loaded with a Uniformly Distr Load *W* (Fig. 9).

Maximum bending moment, at the middle = $Wl/8$

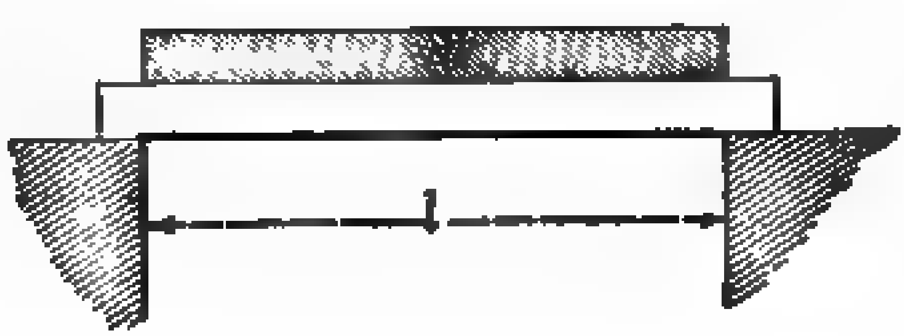

Fig. 9. Simple Beam. Uniformly Distributed Load

Case VI

m Supported at Both Ends and Loaded with a Concentrated Load not at the dle (Fig. 10).

ximum bending moment, under the load = Pmn/l

Fig. 10. Simple Beam. Concentrated Load not at the Middle

Case VII

m Supported at Both Ends and Loaded Symmetrically with Two Equal ntrated Loads (Fig. 11).

ximum bending moment = Pm and is the same for any section of the beam een the two loads.

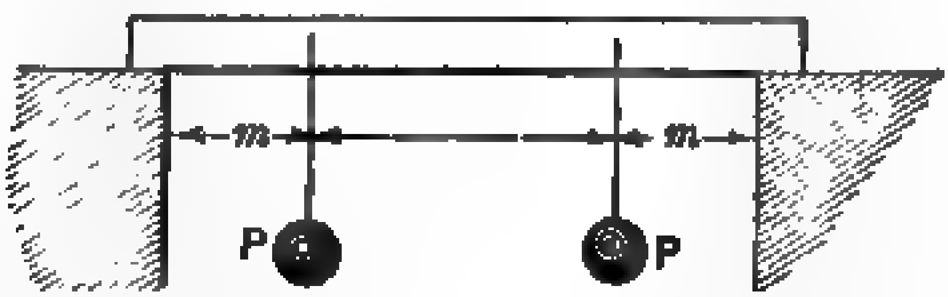

Fig. 11. Simple Beam. Two Concentrated Loads Symmetrically Placed

m these examples it will be seen that all the quantities which enter into computation of the bending moment are the load, the span and the distance e point of application of the load from the center of moments.

Case VIII

m Supported at Both Ends and Loaded with a Distributed Load Over Part e Span (Fig. 12).

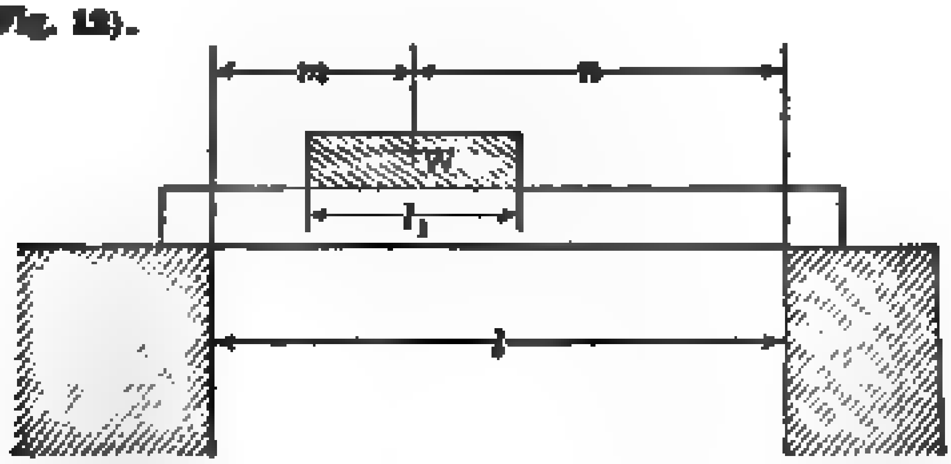

Fig. 12. Simple Beam. Distributed Load over Part of Span

med under the center of the load, $M^*_{max} = Wmn/l - Wl_1/8$
n m and n are equal the bending moment $= W \times l/4 - W \times l_1/8$

is is only approximately correct when m and n are unequal. For the exact value, e section of zero shear; the maximum bending moment will be at that section. lso, Example 5, page 561.)

Example 4. In Fig. 12 let $W = 800$ lb, $m = 8$ ft, $n = 12$ ft, $l = 20$ ft and l_1 =
Then the bending moment

$$= \frac{800 \times 8 \times 12}{20} - \frac{800 \times 8}{8} = 3\,840 - 800 = 3\,040 \text{ ft-lb}, \quad \text{or} \quad 36\,480$$

Example 5. In Fig. 12 let $m = n = 10$ ft, $l = 20$ ft. $l_1 = 4$ ft and $W = 6$
Then the bending moment

$$= \frac{600 \times 20}{4} - \frac{600 \times 4}{8} = 3\,000 - 300 = 2\,700 \text{ ft-lb}, \quad \text{or} \quad 32\,400 \text{ in-lb}$$

The Bending Moment for any Case Other Than the Above may easi obtained by the GRAPHIC METHOD, which will now be explained.

4. Graphic Method of Determining Bending Moments in Bea

Beam with One Concentrated Load (Fig. 13).

The BENDING MOMENT of a beam supported at both ends and loaded wi concentrated load may be determined GRAPHICALLY, as follows:

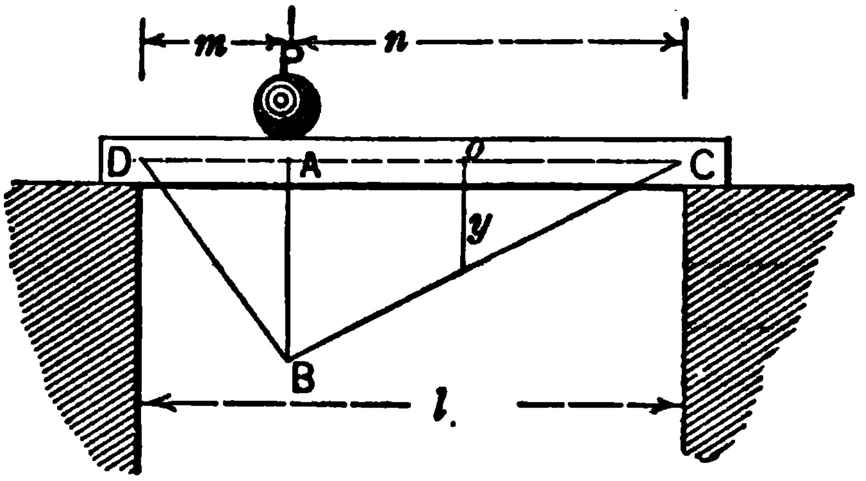

Fig. 13. Bending-moment Diagram. One Concentrated Load

Let P be the applied as shown. by the rule under Ca the MAXIMUM BE MOMENT is under th and $= Pmn/l$

Draw the beam, the given span, acc to scale, and measur the line AB, to a s FOOT-POUNDS to the INCH, a distance to the bending m Connect B with ea of the beam. To find the bending moment at any other point of the as at o, draw the vertical line y to BC. Its length, measured to the scale to which AB is drawn, will give the bending moment at o. The $DBCAD$ is called the BENDING-MOMENT DIAGRAM and the lines BD a are called INFLUENCE LINES for the bending moments.

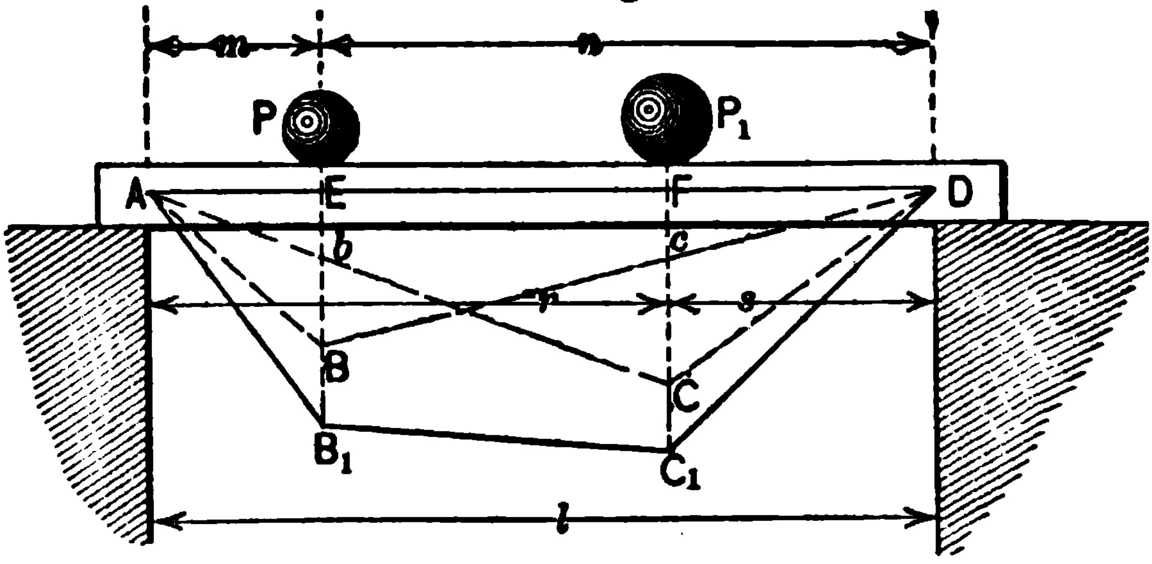

Fig. 14. Bending-moment Diagram. Two Concentrated Loads

Beam with Two Concentrated Loads (Fig. 14).

To draw the bending-moment diagram for a beam with two conce loads, draw the dotted lines ABD and ACD, giving the BENDING-MOME

...ms for each load separately. EB is laid out to scale, equal to Pmn/l and ...C equal to P_1rs/l.

The bending moment at the point E is equal to EB (from the load P) + Eb ...m the load P_1), or $M = EB + Eb = EB_1$; and at F the bending moment is ...ual to $FC + Fc = FC_1$. The BENDING-MOMENT DIAGRAM for both loads is ...CD and the MAXIMUM BENDING MOMENT is, in this particular case, the line ...C measured to scale.

...am with Any Number of Concentrated Loads (Fig. 15.)

Proceed as in the last case, and draw the BENDING-MOMENT DIAGRAM for each ...d separately. Make $AD = A1 + A2 + A3$, $BE = B1 + B2 + B3$ and

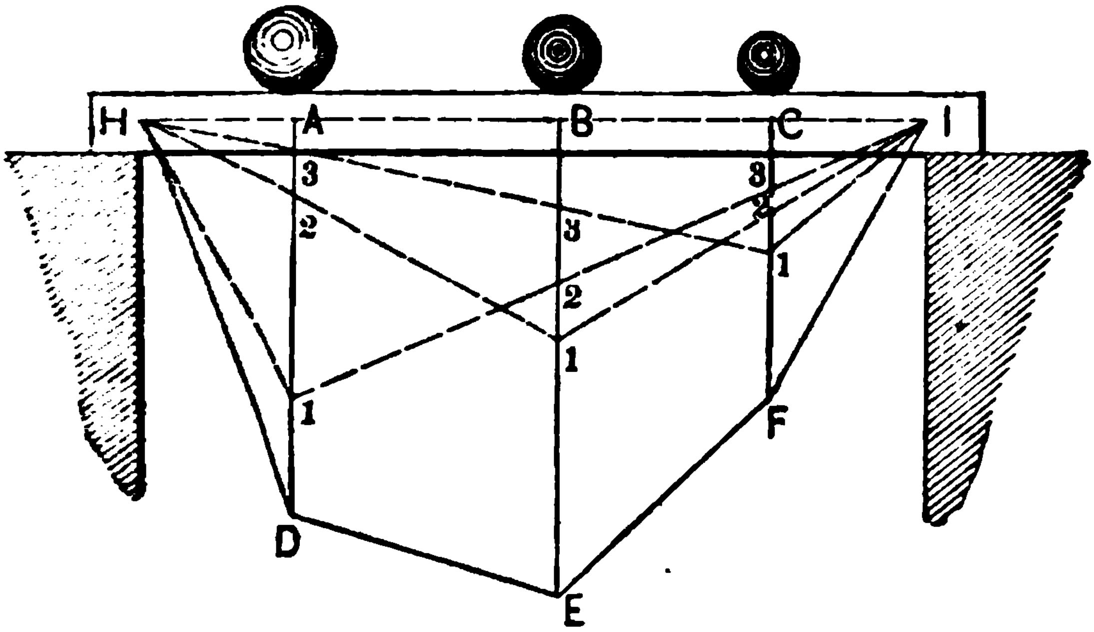

Fig. 15. Bending-moment Diagram. Three Concentrated Loads

...$= C1 + C2 + C3$. The figure $HDEFIH$ will then be the BENDING-MO...NT DIAGRAM corresponding to all the loads. The BENDING-MOMENT DIAGRAM ...a beam with any number of concentrated loads may be drawn in the same ...y.

...am with a Uniformly Distributed Load (Fig. 16).

...aw the beam with the given span, accurately to a scale as before, and at ...middle of the beam draw the vertical line AB, to a scale of a certain number ...FOOT-POUNDS to ... LINEAR INCH, ...al to $Wl/8$, from ...e V, W representing the whole distrib...d load. Connect ...points C, B, D by ...PARABOLA to obtain ...BENDING-MOMENT ...GRAM. To find ...bending moment ...ny point a, draw ...vertical line ab, ...sure it to the ...e scale to which AB is drawn, and it will be the bending moment desired. ...hods for drawing the PARABOLA will be found in Part I, page 79.

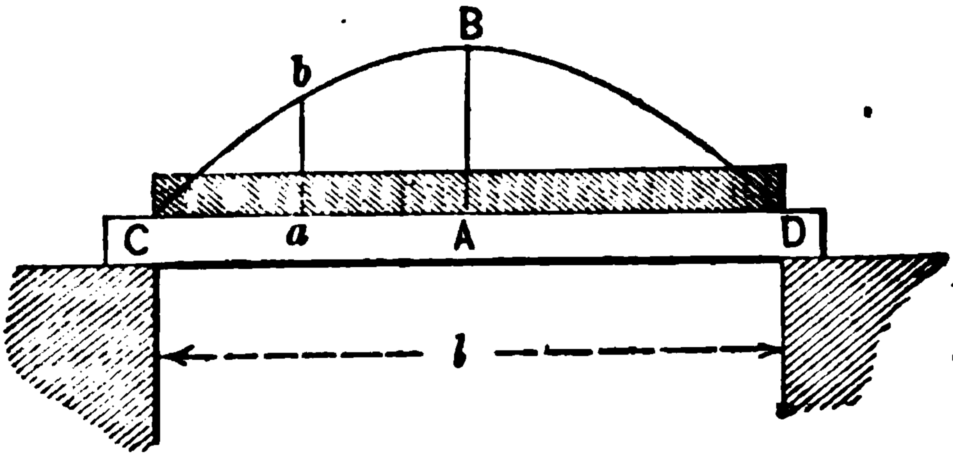

Fig. 16. Bending-moment Diagram. Distributed Load over Whole Beam

...am Loaded with Both Distributed and Concentrated Loads (Fig. 17).

...determine the bending moments in this case, combine the BENDING-MOMENT ...RAMS for the concentrated loads and for the distributed load, as shown in

Fig. 17. The bending moment at any section of the beam will then be lin by the line ABC on top and by the line $CDEFA$ on the bottom; and the 1 IMUM BENDING MOMENT will be the longest vertical line that can be dı

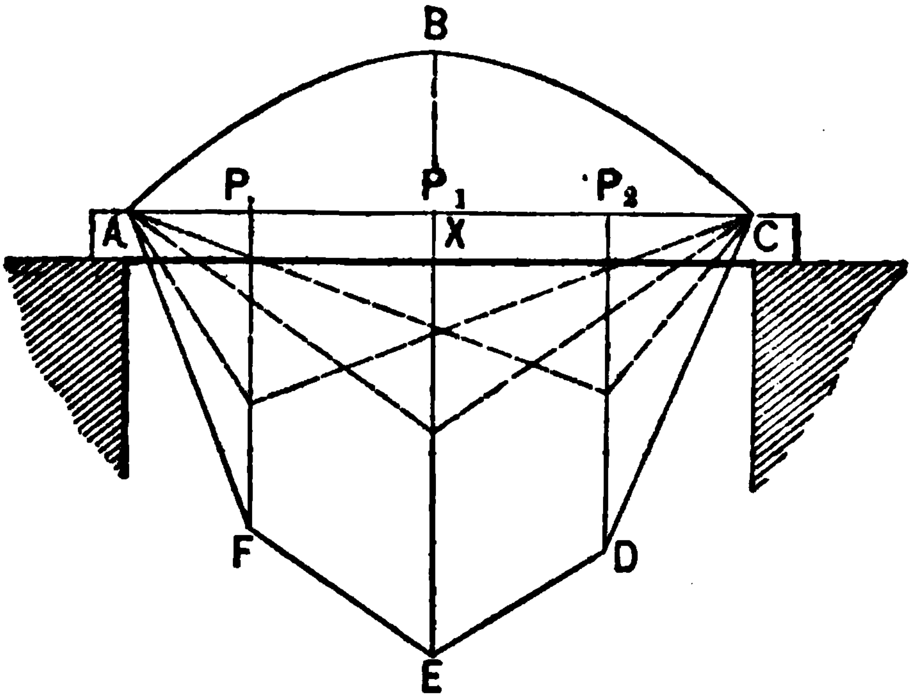

Fig. 17. Bending-moment Diagram. Distributed and Concentrated Loads

between these bounding lines.

For example, bending moment : is BE. The poi MAXIMUM BENDING MENT depends upo position of the co trated loads and relative magnitu the distributed it may or may occur at the mid the beam or unde of the concent loads.

Example 6. ' is the greatest be moment in a bea 20 ft span (Fig. 18), loaded with a distributed load of 800 lb, a concentrated l 500 lb 6 ft from one end, and a concentrated load of 600 lb 7 ft from the other

Solution. (1) The maximum bending moment due to the distributed from Case V, is $Wl/8$, or $800 \times 20/8 = 2\,000$ ft-lb. Lay off vertically ove middle of the beam, and at any convenient scale, say 4 000 ft-lb to the inch, $B1 = 2\,000$ ft-lb, and draw a parabola through the points A, B and C. (See page 79.)

(2) The maximum bending moment for the concentrated load of 500 lb, from Case VI, is $500 \times 6 \times 14/20$, or 2 100 ft-lb. Draw $E2 = 2\,100$ ft-lb to the same scale as $B1$, and then draw the lines AE and CE.

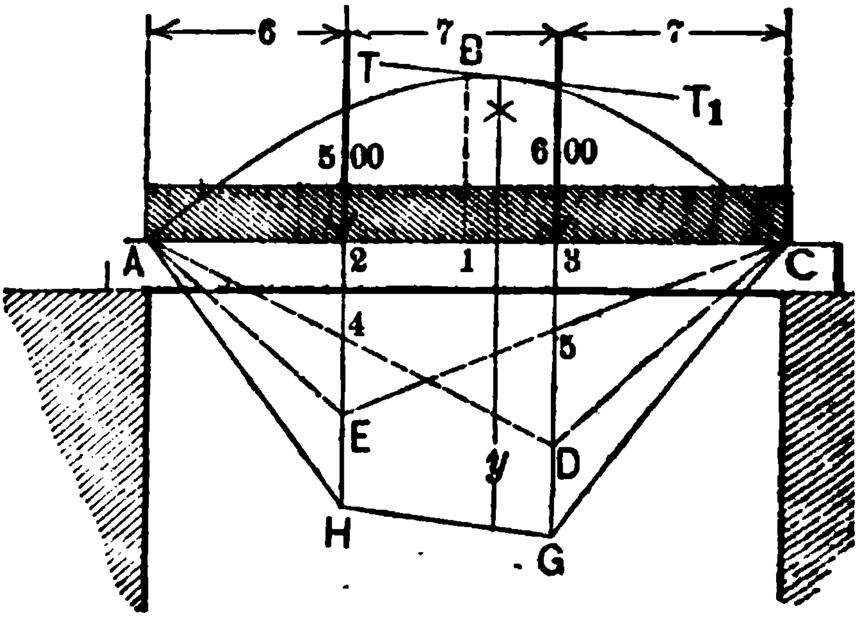

Fig. 18. Bending-moment Diagram. Distributed Concentrated Loads

(3) The maximum bending moment for the concentrated load of 600 like manner, is $600 \times 7 \times 13/20$, or 2 730 ft-lb. Draw $D3 = 2\,730$ ft-ll connect D with A and C.

(4) Make EH equal to the distance from 2 to 4, and DG to the distance 3 to 5, and draw $AHGC$.

The MAXIMUM BENDING MOMENT will be represented by the longest v line which can be drawn between the parabola ABC and the broken line A In this example the longest vertical line which can be drawn is Xy, should scale 5 645 ft-lb.

he position of the line Xy is determined by drawing the line TT_1 parallel C and tangent to ABC. Draw Xy vertically through point of tangency.

actions and Bending Moments for Beams with Triangular Loading and for Beams Fixed at Both Ends.*

ams with Triangular Loading have reactions and bending moments as ws:

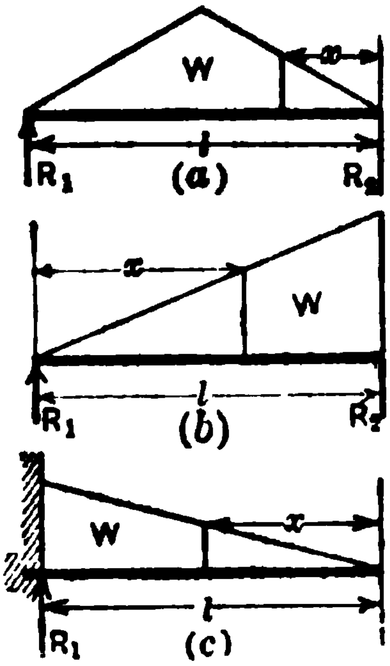

Fig. 19. Triangular Loading on Beams

Beam Supported at Both Ends, Fig. 19 (a)

eactions: $R_1 = R_2 = \frac{1}{2} W$
ing moment at any point $= Wx(\frac{1}{2} - 2x^2/3l^2)$
imum bending moment, at center $= Wl/6$

Beam Supported at Both Ends, Fig. 19 (b)

eactions: $R_1 = \frac{1}{3} W,\ R_2 = \frac{2}{3} W$
ing moment at any point $= (Wx/3)(1 - x^2/l^2)$
imum bending moment (at $x = 0.58\,l$) $= .128\,Wl$

Cantilever Beam, Fig. 19 (c)

tion: $R_1 = W$
ing moment at any point $= Wx^3/3\,l^2$
imum bending moment (at R_1) $= Wl/3$

ams of Cases IV, V, and VI, with Fixed Ends, e reactions and bending moments as follows:

IV A. Beam Fixed at Both Ends, with a Concentrated Load P at the Middle (Fig. 8)

End-reactions: $R_1 = R_2 = \frac{1}{2} P$
Maximum positive bending moment, under the load $= Pl/8$
Maximum negative bending moment, at ends $= Pl/8$

V A. Beam Fixed at Both Ends, with a Uniformly Distributed Load W (Fig. 9)

End-reactions: $R_1 = R_2 = \frac{1}{2} W$
Maximum negative bending moment, at ends $= Wl/12$
Maximum positive bending moment, at center $= Wl/24$

VI A. Beam Fixed at Both Ends, with a Concentrated Load P at Distance m from Left End and Distance n from Right End (Fig. 10)

End-reactions: $R_1 = Pn^2(3m + n)/l^3$; $R_2 = Pm^2(3n + m)/l^3$
Maximum bending moment, negative, at left end, $M_1 = Pmn^2/l^2$
at right end, $M_2 = Pm^2n/l^2$
Bending moment under load, positive $= R_1m - M_1$

CHAPTER X

PROPERTIES OF CROSS-SECTIONS OF STRUCTUR SHAPES. MOMENT OF INERTIA, MOMENT OF RESISTANCE, SECTION-MODULUS, AND RADIUS OF GYRATION

By

CHARLES P. WARREN

LATE ASSISTANT PROFESSOR OF ARCHITECTURE, COLUMBIA UNIVERSI

1. The Properties of Cross-Sections

The Moment of Inertia. The strength of a cross-section to resist s in either a beam or a column, depends not only upon the area but als the form of the cross-section. The parts of the cross-section farthest fr neutral axis, which always passes through the center of gravity of the section, are much more efficient in resisting bending stresses than thos adjacent to the axis; so that some mathematical expression must be ol that will represent the efficiency of the entire cross-section to resist b stresses when compared with that of any other cross-section. This expre called the MOMENT OF INERTIA and is usually designated by the letter I.

The Moment of Inertia of any cross-section may be defined as the the products obtained by multiplying each of the elementary areas of wh section is composed by the square of its normal distance from the neut of the section.

By an ELEMENTARY AREA is meant an area smaller than any dealt simple mathematics, and it is, therefore, impossible to find an exact exp for the moment of inertia of a cross-section by such methods. By means calculus, however, exact formulas have been deduced from which the m of inertia of simple geometrical forms, such as rectangles, triangles, circl may be found, with respect to different axes.

The NEUTRAL AXIS of the cross-section of a beam, girder, column, etc., is in a state of flexure, is the line on which there is neither tension nor co sion in the fibers, and when the unit stresses do not exceed the ELASTIC L the material, it can be shown that this neutral axis passes through the CEN GRAVITY of the cross-section. The normal distance of the extreme fibers fr neutral axis is usually designated by the letter c or the letter y. The fo used in the notation of this book.

Since for all sections except squares and circles, there are, in general, tw tral axes corresponding to the more common positions of the sections, it that there are also two moments of inertia commonly used; for a rectan example, a GREATEST MOMENT OF INERTIA about an axis perpendicular long side and a LEAST MOMENT OF INERTIA about an axis perpendicular short side. The moments of inertia of the cross-sections of all rolled have been calculated and are tabulated in the manufacturers' handbooks. for example, the moments of inertia of the cross-section of a 12-in, 31.5-lb I with respect to axes perpendicular to the web and parallel to the web, ar Table IV, equal to 215.8 and 9.5 biquadratic inches respectively. Formu calculating the moments of inertia of other simple sections are given following pages.

he Moment of Resistance. In Chapter IX, under the chapter-subdivi-
treating of the BENDING MOMENTS in beams, page 325, it was stated that
rder to calculate the FLEXURAL STRENGTH of a beam it is necessary to
tain the nature and extent, first, of the external forces tending to break
beam by flexure, and, secondly, of the internal forces or stresses tending
sist rupture. The external forces cause the BENDING MOMENTS,* and the
nal stresses the MOMENTS OF RESISTANCE, at the various cross-sections of
beam.

he MOMENT OF RESISTANCE or the RESISTING MOMENT at any cross-section
beam is the algebraic sum of all the moments of the internal horizontal
es in that section with reference to a point in that section. It is usually
sented by the expression SI/c, in which S is the horizontal unit stress,
e or compressive, as the case may be, upon the fiber most remote from the
ral axis of the section, and called the FIBER-STRESS; I is the MOMENT OF
RTIA of the area of the section with reference to the NEUTRAL AXIS; and c
he shortest distance from the most remote fiber to that axis. Since, for
ibrium of forces and stresses at any cross-section of a beam, the bending
ent equals the resisting moment for that section, if M represents the bend-
moment we have the equation

$$M = SI/c \tag{1}$$

his is known as the FLEXURE FORMULA and is universally used for investi-
ing the flexural strength of beams.

he Section-Modulus or Section-Factor. That expression I/c in the above
ula is generally known as the SECTION-MODULUS or SECTION-FACTOR.
quantity for the principal rolled sections is given in Tables IV, V, VI, VII,
I, XI, XII, XIII and XIV. Corresponding to the two moments of inertia
ally used for all sections (except for squares and circles) there are two
n-moduli also, one for each axis. Thus, the section-modulus of the 12-in
lb I beam, with respect to a neutral axis perpendicular to the web, is
$= 215.8/6 = 36$; and for the axis parallel to the web, it is $I/c = 9.5/2.5 = 3.8$.
other shapes the section-modulus may be found by dividing the moment of
tia by the normal distance of the extreme fiber from the neutral axis.

he Radius of Gyration. The effect of the form of the cross-section of a
mn on its strength is determined by a quantity called the RADIUS OF GYRA-
I, which is as necessary in the determination of the strength of a column as
moment of inertia is in the determination of the strength of a beam. It is
ted by the letter r. The value of the radius of gyration for any section
termined by the formula

$$r = \sqrt{I/A} \tag{2}$$

hich I is the MOMENT OF INERTIA of the section and A the SECTION-AREA.
RADIUS OF GYRATION is the normal distance from the NEUTRAL AXIS to the
ER OF GYRATION, and the center of gyration of a section is the point where
ntire area might be concentrated and have the same moment of inertia
e actual distributed area. The radius of gyration of a section is a DISTANCE
h is always less than the distance, c, from the neutral axis to the remotest
. For the two moments of inertia above referred to, and commonly used,
are two corresponding radii of gyration. The least of these is the one to be
in the investigation of the strength of a column as it is referred to the axis
t which the column is most likely to fail. The radii of gyration of the rolled

* See Chapter IX, page 325, for definition of "bending moment."

shapes are given in the tables of the properties of sections, mentioned a For the 12-in 31.5-lb I beam, $r = 4.83$ in and $r' = 1.01$ in. The radius of gyı of any other section may be found by Formula (2).

Formulas for the moments of inertia, radii of gyration and section-m of the principal elementary sections are given on the following pages.] case of a hollow section or a section with a reentering hollow part, the mc of inertia of the hollow part is to be subtracted from that of the enclosing Moments of inertia when referred to the same axis can be added or subtı like any other quantities which are of the same kind.

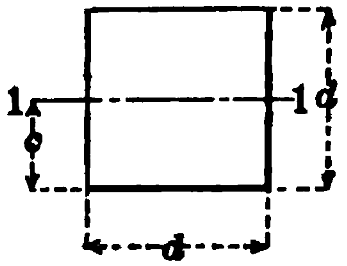
2. Areas, Moments of Inertia, Section-Moduli and Radii of Gyration of Elementary Sections

I = the moment of inertia
I/c = the section-modulus
r = the radius of gyration
A = the area of the section
c = the normal distance of most remote fiber from neutral axi

The position of axis referred to in each case is represented by the broke 1 — 1.

SQUARE

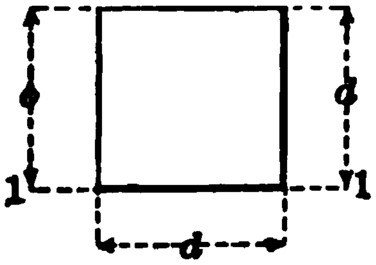
Axis of moments through center



$$A = d^2$$
$$c = \frac{d}{2}$$
$$I = \frac{d^4}{12}$$
$$\frac{I}{c} = \frac{d^3}{6}$$
$$r = \frac{d}{\sqrt{12}} = 0.288675\,d$$

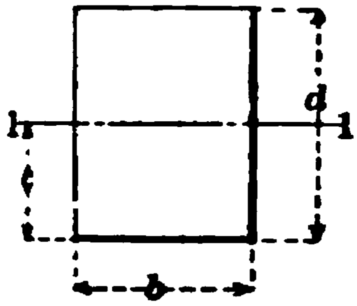
SQUARE

Axis of moments on base



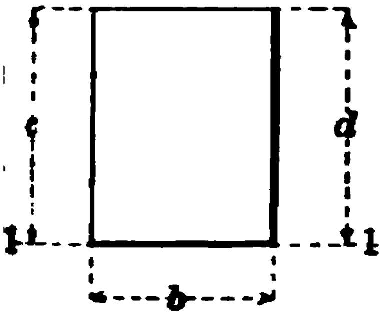
$$A = d^2$$
$$c = d$$
$$I = \frac{d^4}{3}$$
$$\frac{I}{c} = \frac{d^3}{3}$$
$$r = \frac{d}{\sqrt{3}} = 0.577350\,d$$

RECTANGLE
his of moments through center



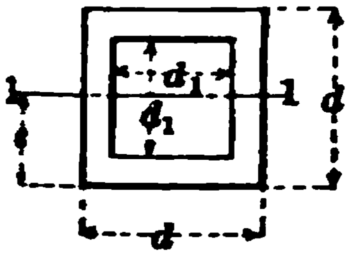
$$A = bd$$
$$c = \frac{d}{2}$$
$$I = \frac{bd^3}{12}$$
$$\frac{I}{c} = \frac{bd^2}{6}$$
$$r = \frac{d}{\sqrt{12}} = 0.288675\,d$$

RECTANGLE
his of moments on base



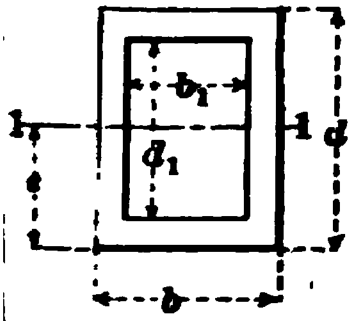
$$A = bd$$
$$c = d$$
$$I = \frac{bd^3}{3}$$
$$\frac{I}{c} = \frac{bd^2}{3}$$
$$r = \frac{d}{\sqrt{3}} = 0.577350\,d$$

HOLLOW SQUARE
his of moments through center



$$A = d^2 - d_1^2$$
$$c = \frac{d}{2}$$
$$I = \frac{d^4 - d_1^4}{12}$$
$$\frac{I}{c} = \frac{d^4 - d_1^4}{6\,d}$$
$$r = \sqrt{\frac{d^2 + d_1^2}{12}}$$

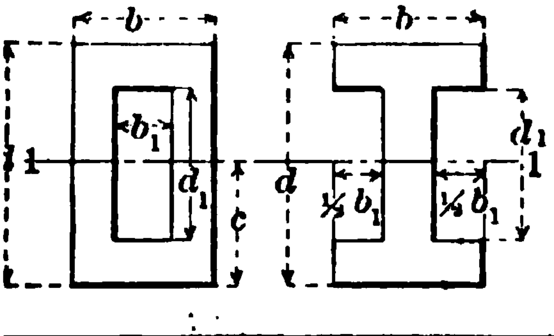
LLOW RECTANGLE
s of moments through center



$$A = bd - b_1d_1$$
$$c = \frac{d}{2}$$
$$I = \frac{bd^3 - b_1d_1^3}{12}$$
$$\frac{I}{c} = \frac{bd^3 - b_1d_1^3}{6\,d}$$
$$r = \sqrt{\frac{bd^3 - b_1d_1^3}{12\,(bd - b_1d_1)}}$$

HOLLOW RECTANGLE AND I BEAM

Axis of moments through center



$$A = bd - b_1d_1$$

$$c = \frac{d}{2}$$

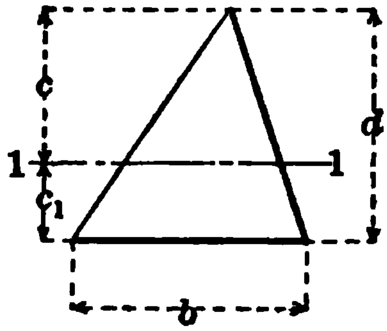
$$I = \frac{bd^3 - b_1d_1^3}{12}$$

$$\frac{I}{c} = \frac{bd^3 - b_1d_1^3}{6\,d}$$

$$r = \sqrt{\frac{bd^3 - b_1d_1^3}{12\,(bd - b_1d_1)}}$$

TRIANGLE

Axis of moments through center of gravity



$$A = \frac{bd}{2}$$

$$c = \frac{2\,d}{3} \qquad c_1 = \frac{d}{3}$$

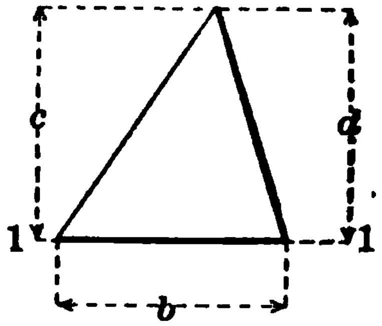
$$I = \frac{bd^3}{36}$$

$$\frac{I}{c} = \frac{bd^2}{24}$$

$$r = \frac{d}{\sqrt{18}} = 0.235702\,d$$

TRIANGLE

Axis of moments on base



$$A = \frac{bd}{2}$$

$$c = d$$

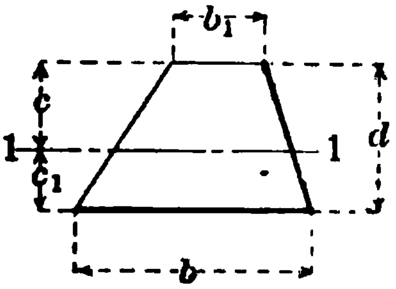
$$I = \frac{bd^3}{12}$$

$$\frac{I}{c} = \frac{bd^2}{12}$$

$$r = \frac{d}{\sqrt{6}} = 0.408248\,d$$

TRAPEZOID

Axis of moments through center of gravity



$$A = \frac{d\,(b + b_1)}{2}$$

$$c^* = \frac{d\,(b_1 + 2\,b)}{3\,(b + b_1)} \qquad {}^*c_1 = \frac{d\,(b +}{3\,(b -}$$

$$I = \frac{d^3\,(b^2 + 4\,bb_1 + b_1^2)}{36\,(b + b_1)}$$

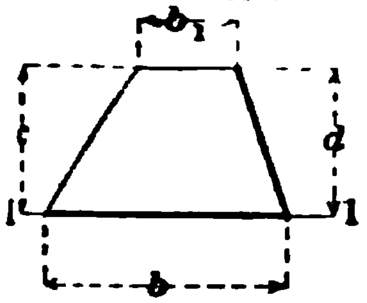
$$\frac{I}{c} = \frac{d^2\,(b^2 + 4\,bb_1 + b_1^2)}{12\,(b_1 + 2b)}$$

$$r = \frac{d}{6\,(b + b_1)}\sqrt{2\,(b^2 + 4bb_1}$$

* To find c and c_1, see Chapter VI, page 295.

TRAPEZOID

Axis of moments on base



$$A = \frac{d(b + b_1)}{2}$$

$$c = d$$

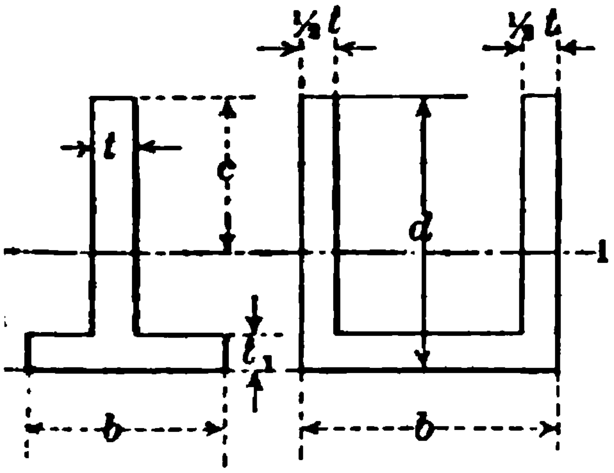
$$I = \frac{d^3(b + 3b_1)}{12}$$

$$\frac{I}{c} = \frac{d^2(b + 3b_1)}{12}$$

$$r = \frac{d}{\sqrt{6}}\sqrt{\frac{b + 3b_1}{b + b_1}}$$

T SECTION AND CHANNEL

Axis of moments through center of gravity



$$A = td + t_1(b - t)$$

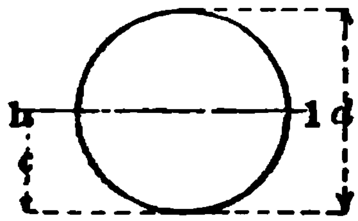
$$c^* = \frac{td \times \frac{1}{2}d + t_1(b - t)(d - \frac{1}{2}t_1)}{A}$$

$$I = \frac{tc^3 + bc_1^3 - (b - t)(c_1 - t_1)^3}{3}$$

$$r = \sqrt{\frac{I}{A}}$$

CIRCLE

Axis of moments through center



$$A = \frac{\pi d^2}{4} = 0.785398\,d^2$$

$$c = \frac{d}{2}$$

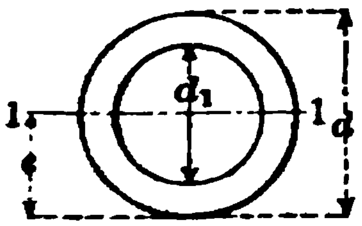
$$I = \frac{\pi d^4}{64} = 0.049087\,d^4$$

$$\frac{I}{c} = \frac{\pi d^3}{32} = 0.098175\,d^3$$

$$r = \frac{d}{4}$$

HOLLOW CIRCLE

Axis of moments through center



$$A = \frac{\pi(d^2 - d_1^2)}{4} = 0.785398\,(d^2 - d_1^2)$$

$$c = \frac{d}{2}$$

$$I = \frac{\pi(d^4 - d_1^4)}{64} = 0.049087\,(d^4 - d_1^4)$$

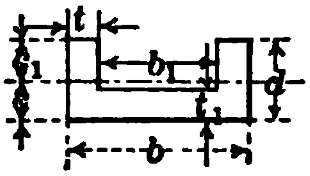
$$\frac{I}{c} = \frac{\pi(d^4 - d_1^4)}{32\,d} = 0.098175\,\frac{(d^4 - d_1^4)}{d}$$

$$r = \frac{\sqrt{d^2 + d_1^2}}{4}$$

* To find the values of c and c_1, see Chapter VI, page 295.

CHANNEL

Axis of moments through center of gravity



$$A = t_1b + 2t(d - t_1)$$

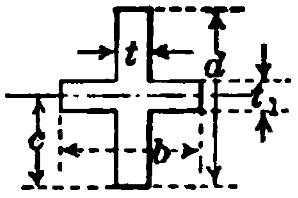
$$c^* = \frac{2d^2t + b_1t_1^2}{2A}$$

$$I = \frac{2td^3 + b_1t_1^3}{3} - Ac^2$$

$$r = \sqrt{\frac{I}{A}}$$

CROSS-SECTION

Axis of moments through center of gravity



$$A = td + t_1(b - t)$$

$$c = \frac{d}{2}$$

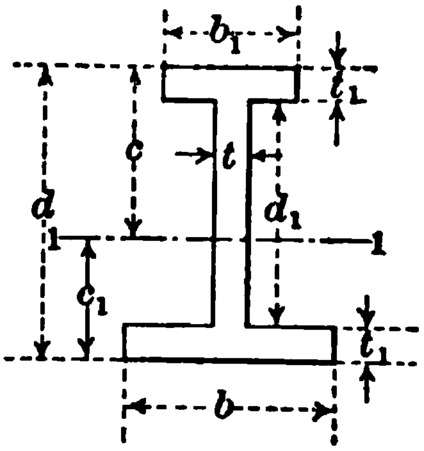
$$I = \frac{td^3 + t_1^3(b - t)}{12}$$

$$\frac{I}{c} = \frac{td^3 + t_1^3(b - t)}{6d}$$

$$r = \sqrt{\frac{td^3 - t_1^3(b - t)}{12(td + t_1(b - t))}}$$

IRREGULAR I SHAPE

Axis of moments through center of gravity



$$A = bt_1 + d_1t + b_1t_1$$

$$c^* = \frac{td^2 + t_1^2(b_1 - t) + t_1(b - t)(2d -}{2A}$$

$$c_1 = \frac{td^2 + t_1^2(b - t) + t_1(b_1 - t)(2d -}{2A}$$

$$I = \frac{b_1c^3 - (b_1 - t) \times (c - t_1)^3}{3} + \frac{bc_1^3 - (b - t) \times (c_1 - t_1)^3}{3}$$

$$r = \sqrt{\frac{I}{A}}$$

* To find c and c_1, see Chapter VI, page 295.

3. Transferring Moments of Inertia to Other Parallel Axes

Explanation of Formula. It is often necessary to determine the m of inertia with respect to some other axis than the one passing throu center of gravity of the section, such, for example, as one passing throu base and parallel to the other. Suppose it is desired to find the moment ertia of a rectangle about an axis passing through the lower base, as second figure on page 335. It may be demonstrated by the princi mechanics that the moment of inertia of any section with respect to an is equal to the moment of inertia of the section with respect to a parall through the center of gravity, plus the product of the area of the section plied by the square of the normal distance between the axes. This rule r expressed by the formula

$$I_1 = I + Ah^2$$

wich I_1 is the required moment of inertia, I the moment of inertia of the tion with respect to the axis through its center of gravity and parallel to the n axis, A the area of the section and h the normal distance between the axes. m this it is seen that the moment of inertia of any section-area is less for axis through its center of gravity than for any other parallel axis.

For example, consider the rectangle shown on page 335, of breadth b and th d, the I of which is known to be $bd^3/12$ for an axis passing through the ter of gravity and parallel to the base. Then, for allel axis through the base, the above formula es

$$I_1 = \frac{bd^3}{12} + bd \times \left(\frac{d}{2}\right)^2 = \frac{bd^3}{12} + \frac{bd^3}{4} = \frac{bd^3}{3}$$

hus the moment of inertia of the cross-section he steel angle shown in Fig. 1, about the axis N, is equal to the moment of inertia about the s XX plus the product of its area multiplied h^2. The moments of inertia for the sections of standard rolled shapes of structural steel may found from the tables given in this chapter. The ance c_1, also, may be found from the same tables; this distance subtracted from d will give the ance h of Formula (3).

Suppose, for example, that it is desired to find the ment of inertia of the cross-section of a 4 by 3 in angle, placed, with the long leg horizontal, t an axis MN, 12 in from the back (Fig. 1). Turning to Table XI, the of the angle-section = 3.25 sq in. I, the moment of inertia of the angle-ion about an axis 2–2, or XX of Fig. 1, parallel to the long leg = 2.4, c_1, the ance of this axis from the back of the long leg = 0.83 in and h, the distance een the axes = $(d - c_1)$ = 12 − 0.83 in = 11.17 in. Substituting these values ormula (3)

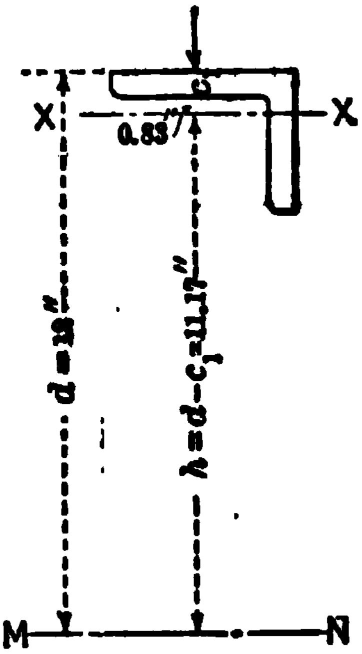


Fig. 1. Moment of Inertia of Cross-section of Steel Angle.

$$I_1 = 2.4 + 3.25 \times 11.17^2 = 2.4 + 405.50 = 407.9$$

4. Moments of Inertia of Compound Sections

he Moment of Inertia of a Compound Section made up of a number of ler sections may be found by the same formula, $I_1 = I + Ah^2$. Denote the OF THE MOMENTS OF INERTIA of the separate sections making up the com-d section, with respect to an axis through the center of gravity of that m, by ΣI_1. Formula (3) then becomes

$$\Sigma I_1 = \Sigma\,(I + Ah^2) \qquad (4)$$

at is, to find the moment of inertia of any compound section made up of mber of smaller sections:

Find the moment of inertia of each of the smaller sections about an axis g through its own center of gravity and parallel to the neutral axis of the ound section;

Multiply the area of each of the smaller sections by the square of the dis-between its center of gravity and the center of gravity of the whole figure;

Add the results found by (1) and (2) for the moment of inertia of the e figure.

r example, consider the cast-iron beam or lintel shown in section in Fig. 2:

(1) I of upper flange-section $= 4 \times 1^3/12 = 4/12$
I of web-section $= 1 \times 18^3/12 = 5\,832/12$
I of lower flange-section $= 16 \times 1^3/12 = 16/12$
Total $= 5\,852/12 = 487.6$

(2) Ah^2 for the upper flange $= 4 \times (12.5)^2 = 625$
Ah^2 for the web $= 18 \times 3^2 = 162$
Ah^2 for the lower flange $= 16 \times (6.5)^2 = 676$
Total $= 1\,463$

(3) Total of (1) and (2) $= 487.6 + 1\,463 = I_1$ of compound section $= 1\,9$

The moment of inertia of the cross-section of any compound beam, then can generally be readily found by using the tables of properties of sections

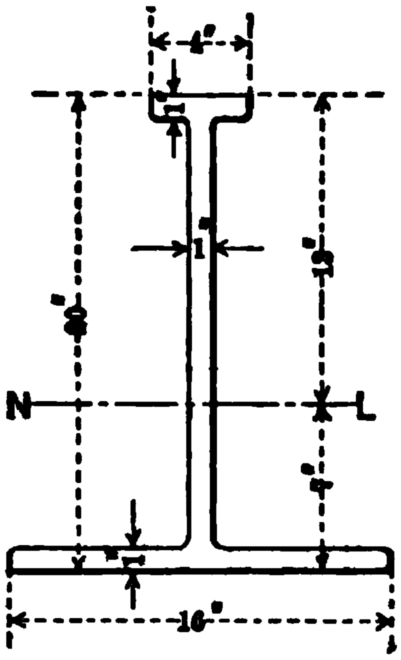

Fig. 2. Moment of Inertia of Cross-section of Cast-iron Lintel

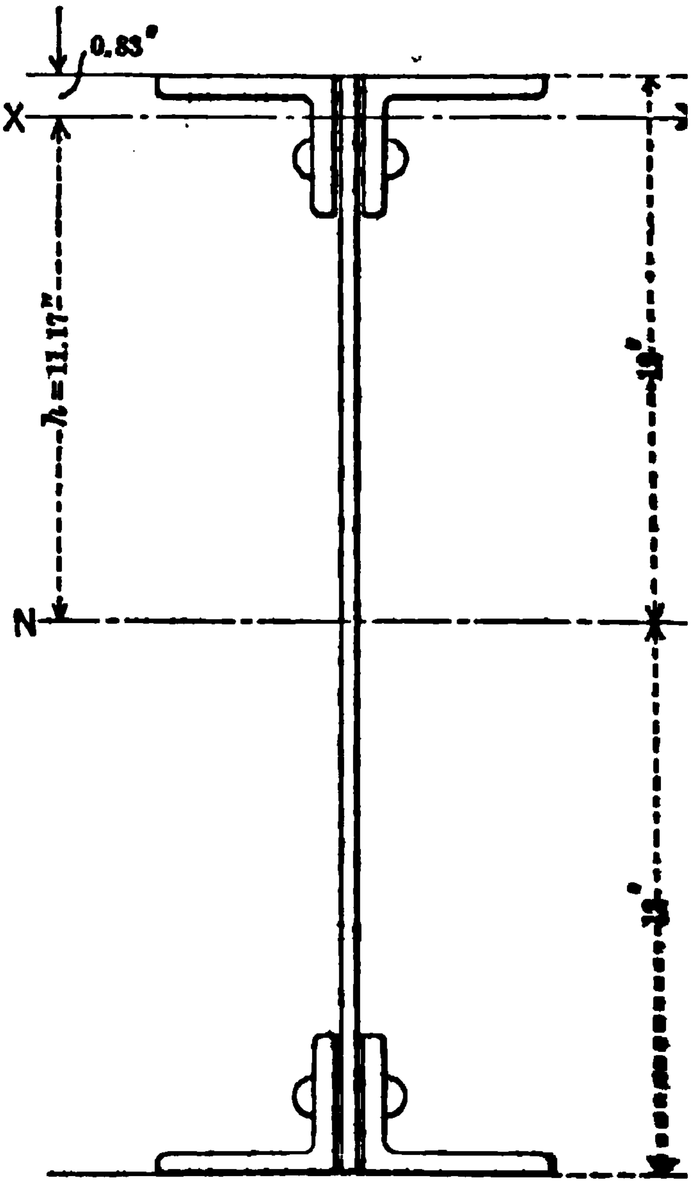

Fig. 3. Moment of Inertia of Cross-sect of Plate Girder. No Flange-plates

give the numerical values of I for the various rolled shapes of which the beam is composed, with respect to the axis through the center of gravity.

The Moment of Inertia of a Single-Web Girder-Section. Consider, for example, the single-web girder shown in section in Fig. 3, and made up of one ½ by 24-in web and four 4 by 3 by ½-in flange-angles with the long legs placed horizontally. ing to Table XI, the moment of inertia of the cross-section of o these angles about an axis XX (2–2 in the table) parallel to the leg = 2.4, and the distance of this axis from the back of the long leg (y table) = 0.83 in; hence h, the distance between the axis of the angle-s and the axis of the girder-section = 12 − 0.83 = 11.17 in. A, from the = 3.25 sq in. The moment of inertia of the cross-section of each angle the axis of the girder, therefore, from Formula (3), is $I_1 = 2.4 + 3.25 \times (11$ 407.9, and for the four angles = 1631.6. Since the axis of the cross-sect

web-plate is coincident with the axis of the section of the girder, its moment of inertia = $bd^3/12$ = $\frac{1}{2} \times (24)^3/12 = 576$. This may be found directly from Table I, page 346, Moments of Inertia of Rectangles. The moment of inertia, therefore, of the section of the compound girder = 1631.6 + 576 = 2207.6.

The Moment of Inertia of a Section of a Compound Girder with Flange-Plates is found in the same way, except that the moments of inertia of the sections of the flange-plates with respect to the axis of the girder-section must be added to the moments of inertia of the cross-sections of the other members. The girder in Fig. 4 is composed of one 30 by 3/8-in web-plate, four 6 by 4 by 9/16-in angles, with the longer legs horizontal, and two 12 by ½-in flange-plates.

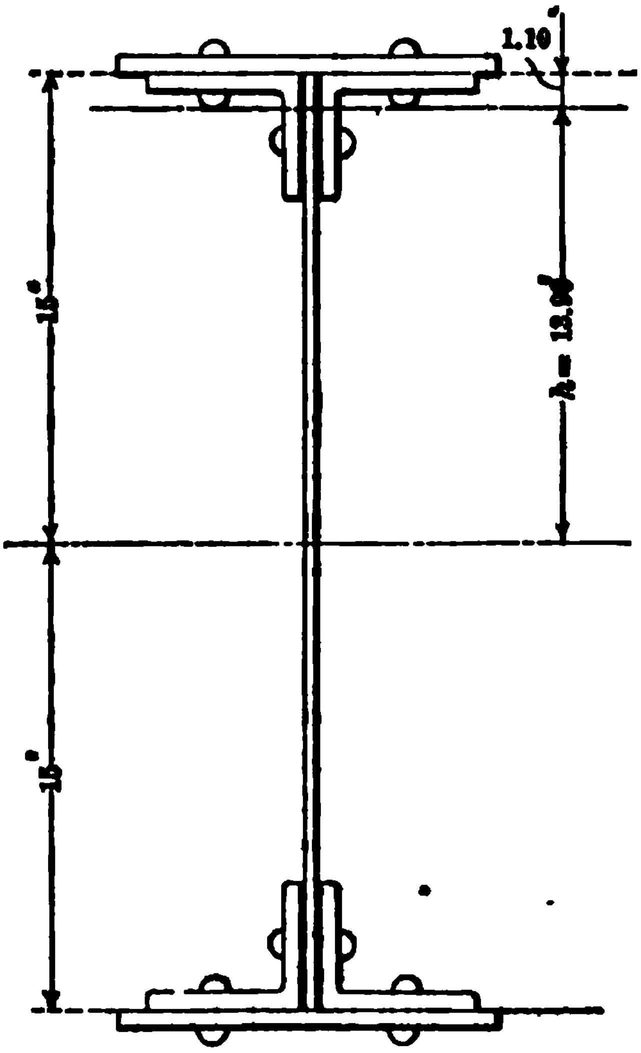

Fig. 4. Moment of Inertia of Cross-section of Plate Girder with Flange-plates

I (= I_1) for cross-section of web (from Table I, page 346) = 843.75

I_1 for each angle-section = $I + Ah^2$ (Formula 3)

From Table XI, for each flange-angle, I = 6.6, A = 4.75 and the perpendicular distance from center of gravity to back of long leg = 1.10 in. Hence $h = 15 - 1.10 = 13.90$ in. $I_1 = 6.6 + 4.75 \times (13.90)^2 = 924.35$; and for four angles 3697.4. I for the cross-section of each flange-plate = $12 \times (\frac{1}{2})^3/12 = 0.125$, $A = \frac{1}{2} \times 12 = 6$ sq in and $h = 15 + \frac{1}{4} = 15.25$ in. For each flange-plate, then, $I_1 = 0.125 + 6 \times (15.25)^2 = 1395.125$; and for the two plates, 2 790.25. The moment of inertia for the cross-section of the whole girder, therefore, with reference to the horizontal axis passing through the center of gravity of the section = 843.75 + 3 697.4 + 2 790.25 = 7 331.4.

It will be noticed that the moments of inertia of the cross-sections of the flange-plates and angles about their own neutral axes is so small, compared with their moments of inertia about the neutral axis of the girder-section, that they might be omitted without any appreciable error. Therefore, in calculating the moments of inertia for riveted girders, it is the custom of many engineers to let $I_1 = Ah^2$ for flange-plate and angle-sections. In that case, for the girder-section in Fig. 4,

I for web	= 843.75
I_1 for angles = Ah^2	= 3 671.00
I_1 for flange-plates = Ah^2	= 2 790.00
Moment of inertia of entire girder-section	= 7 304.75

The Moment of Inertia of a Section of a Box Girder. Let the box girder shown in Fig. 5 be composed of two 3/8 by 30-in webs, two 16 by ½-in plates and four 4 by 3 by ½-in angles with the long legs horizontal.

I for each flange-plate $= bd^3/12 = 16 \times (\frac{1}{2})^3/12 = 0.16$; $A = \frac{1}{2} \times 16$ in $= 8$ and $h = 15 + \frac{1}{4} = 15.25$ in. $I_1 = I + Ah^2 = 0.16 + 8 \times (15.25)^2 = 1\,860.64$; for the two flange-plates, 3 721.28. I for angle $= 2.4$, $A = 3.25$ and the distance fro back of the long leg to an axis throug center of gravity of the angle, parallel t long leg $= 0.83$ in; so that $h = 15 - 0.83 =$ in. I_1 for the four angles is $(4 \times 2.4) +$ $3.25) \times (14.17)^2 = 2\,619$. I for each web (I, page 346) $= 843.75$ and for the two $= 1\,687.5$. The moment of inertia, therefore, for the entire girder-section $=$ $3\,721.28 + 2\,619 +$ $1\,687.5 = 8\,027.78$.

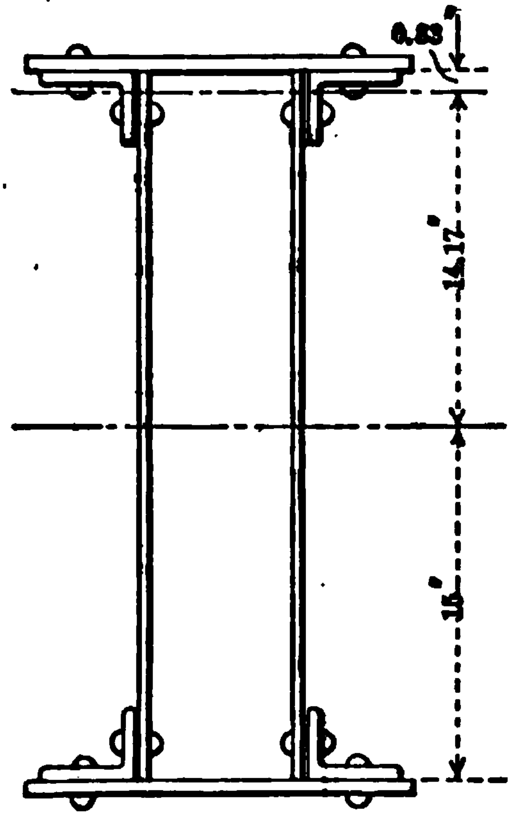

Fig. 5. Moment of Inertia of Cross-section of Plate-and-angle Box Girder

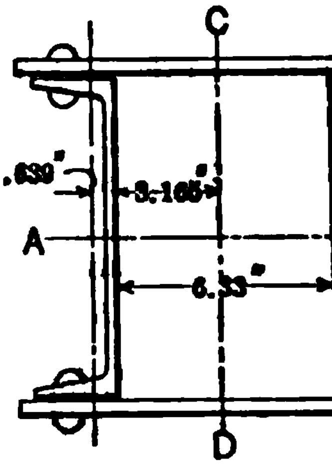

Fig. 6. Moment of of Cross-section o and-channel Box C

The Moment of Inertia of the Section of a Channel Box Column. Fig. 6 shows the cross-section of a column made up of two 10-in 15.3-lb channels, set 6.33 in apart, back to back, and two ½ by 12-in side plates. Let it be required to fin moment of inertia of the section about the two axes AB and CD.

(1) Find the moment of inertia about the axis AB. I, for one of t plates with respect to an axis through its own center of gravity and par $AB = 12 \times (\frac{1}{2})^3/12 = 0.125$, $A = \frac{1}{2} \times 12$-in $= 6$ sq in and the distance of its center of gravity from AB is 5.25 in. Therefore, with respect to AB, $I_1 = 0.125 + 6 \times (5.25)^2$ $= 165.5$. The moment of inertia of a 10-in 15.3-lb channel with respect to an axis through its center of gravity and perpendicular to the web (Table VIII, page 359) $= 66.9$. Hence the moment of inertia of the whole column-section with respect to the axis AB $= (2 \times 165.5) + (2 \times 66.9)$ $= 464.8$.

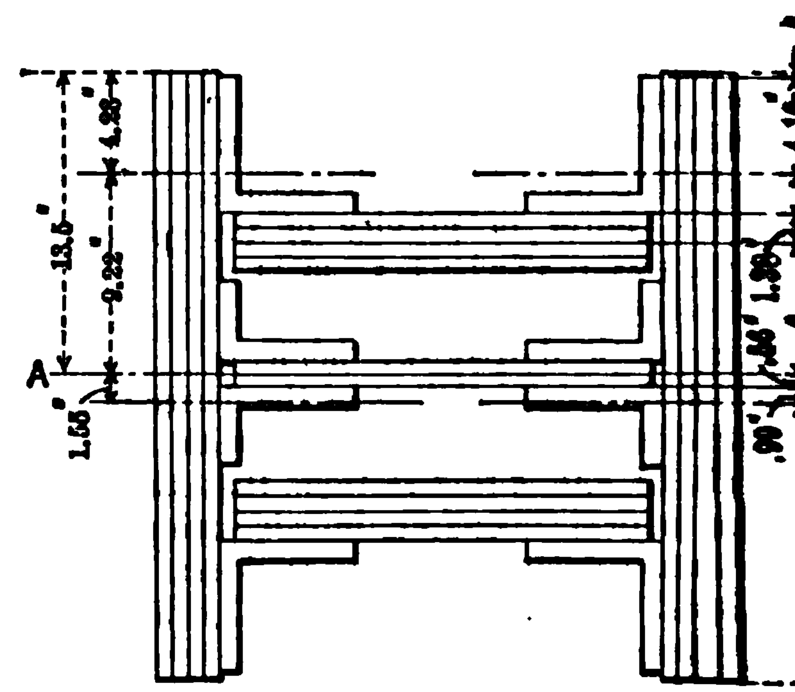

Fig. 7. Moment of Inertia of Cross-section of web Plate-and-angle Box Column

(2) Find the moment of inertia about the axis CD. I, for one of the side plates (Table 346) $= 72$. I, for one of the channels with respect to an axis parallel web $= 2.30$, $A = 4.47$ and the distance of the center of gravity from t of the web $= 0.64$ in, approximately. Hence $h = 3.165 + 0.64 =$ $I_1 = 2.30 + 4.47 \times (3.8)^2 = 66.8$ and the moment of inertia of the whole section with respect to the axis $CD = (2 \times 72) + (2 \times 66.8) = 277.6$.

he Moment of Inertia of the Section of a Heavy Plate-and-Angle mn. Fig. 7 shows the cross-section of one of the basement-columns in Bankers' Trust Company Building, New York City. It is made up of six e-plates, each 27 by ¾ in section; two flange-plates, each 27 by 1 1/16 in; r flange-angles, each 6 by 6 by 15/16 in; eight outer web-plates, each 18 by in; four web-angles, each 6 by 3½ by 15/16 in; and two middle web-plates h 18 by 9/16 in. What is its moment of inertia of the entire column-section h respect to the axis AB?

I for each 27 by ¾-in flange-plate (Table I) = 1 230.19	
I for six 27 by ¾-in flange-plates = 1 230.19 × 6 =	7 381.14
I for each 27 by 1 1/16-in flange-plate (Table I) = 1 127.67	
I for two 27 by 1 1/16-in flange-plates = 1 127.67 × 2 =	2 255.34
I for both flanges	9 636.48

or the flange-angles (Table XII, page 366) the area of a 6 by y 15/16-in angle = 10.37, its I with respect to an axis parallel to (Fig. 7) and passing through its center of gravity = 33.7 and distance of this axis from the back of the leg = 1.84 in. Its I_1 h respect to the axis AB is found by Formula (3), page 338, $I + Ah^2$. $h = 13.5 - (0.12 + 4.16)$ = the distance from the axis to the parallel axis through the center of gravity of the angle 22 in. Hence, substituting in Formula (3),

$$I_1 = 33.7 + 10.37 \times (9.22)^2 = 915.15$$

I_1 for the four flange-angles = 915.15 × 4 = 3 660.60

ach outer web is 4 × 11/16 in = 2¾ in thick. Hence the I for outer web about the horizontal axis through its center of ity = $18 \times (2.75)^3/12$ = 31.2. A = 18 by 2.75 in = 49.5 sq in. distance from its center of gravity to the axis AB is 13.5 − (1.38 + 4.16 + 0.12) = 6.01 or, say 6 in.

m Formula (3), therefore, $I_1 = 31.2 + 49.5 \times 6^2 = 1\,813.2$ and both outer webs $I_1 = 1\,813.2 \times 2$ = 3 626.4

r the four web-angles, from Table XI, page 363, the area of a 3½ by 15/16-in angle = 8.03, its I with respect to an axis through ter of gravity and parallel to the long leg = 6.9 and the dis- e of this axis from the back of the long leg = 0.99 in. h, the total distance between the two axes = 9/16 in, or 0.5625 in thickness of one of the middle web-plates) + 0.99 = 1.55 in, ximately. Therefore, for one web-angle, from Formula (3),

$$I_1 = 6.9 + 8.03 \times (1.55)^2 = 26.17$$

for the four angles, $I_1 = 26.17 \times 4$ = 104.68

e middle web-plates are together 9/16 in × 2 = 1⅛ in = 1.125 ck. The I (= I_1) for the two plates is $18 \times (1.125)^3/12$ = 2.14

e moment of inertia of the entire column-section for the axis , therefore, the sum of these moments of inertia for the differ- arts:

I_1 for the eight flange-plates	9 636.48
I_1 for the four flange-angles	3 660.60
I_1 for the eight outer web-plates	3 626.40
I_1 for the four web-plates	104.68
I_1 for the middle web-plates	2.14
The moment of inertia for the entire section	17 030.30

5. Radii of Gyration of Compound Sections

The Radius of Gyration of any Compound Section may be found f Formula (2), page 333, by dividing the moment of inertia of the section by total area of the section and taking the square root of the quotient. T the radii of gyration of the channel-column section shown in Fig. 6, about axes AB and CD, are found as follows: $A =$ (the sum of the areas of two 12-in plates, or 12 sq in) + (the sum of the areas of the two channels, or sq in) = 20.94 sq in. I about $AB = 464.8$ and about $CD = 277.6$.

Therefore, r, with respect to the axis $AB = \sqrt{\dfrac{464.8}{20.94}} = 4.71$

and r_1, with respect to the axis $CD = \sqrt{\dfrac{277.6}{20.94}} = 3.64$

Since r_1 is the smaller, it is the value to be used in the column-formula. to be noted that this value of r agrees with the r of the 10-in channel-colu Table XXV, on page 533. The value of r_1 does not, however, agree exactly the r_1 in the same table, the variation being caused by a difference in the sp of the channels, back to back.

The Least Radius of Gyration of a Section of a Plate-and-A Column. As another example, let it be required to find the least radi gyration of the cross-section of the plate angle column shown in Fig. 8, made up o 3/8 by 12-in web-plate, two 3/8 by 12-in side and four 4 by 4 by 1/2-in angles.

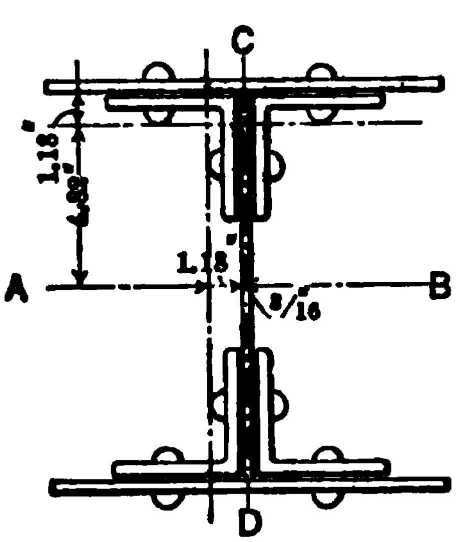

Fig. 8. Least Radius of Gyration of Cross-section of Plate-and-angle Column

(1) Find the moment of inertia about th AB. For the axis AB, I for each one of th plates with respect to an axis through its center of gravity and parallel to the axis $12 \times (3/8)^3/12 = 0.05$. $A = 3/8 \times 12 = 4.5$ sq $h = 6 3/16$ in. $I_1 = 0.05 + 4.5 \times (6 3/16)^2 =$ 1 I for each one of the angles with respect axis through its center of gravity and p with the flange-leg is 5.6, $A = 3.75$ and th tance of the center of gravity from the ba the flange of the angle = 1.18. Hence, h − 1.18 in = 4.82 in and h for each angle + $3.75 \times (4.82)^2 = 92.71$. I for the web-p 54. The moment of inertia of the whole column-section, therefore, abo axis $AB = (2 \times 172.33) + (4 \times 92.71) + 54 = 769.50$.

(2) Find the moment of inertia about the axis CD. I for each side = 54. I for each angle = 5.6 and A for each angle = 3.75. The distan the center of gravity of each angle from the back of the flange of the = 1.18 in and hence, $h = 1.18$ in + 3/16 in = 1.36 in, approximately. I_1 fo angle = $5.6 + 3.75 \times (1.36)^2 = 12.54$. I for each web-plate = 0.05. The m of inertia of the whole column-section, therefore, about the axis $CD =$ (2 × $(4 \times 12.54) + 0.05 = 158.21$.

Since this is the least moment of inertia the least radius of gyration wil wise be about the axis CD. The area of the cross-section of the column = 3.75, the area of the angles) + (3 × 4.5, the area of each plate) = 28.5. $158.21/28.5 = 5.55$ and r, the least radius of gyration = 2.35.

The Radius of Gyration of the Cross-Section of a Hollow Rectangular Column. As another example, let it be required to find the radius of gyration of the cross-section of a hollow rectangular cast-iron column with outside dimensions 6 by 6 in and with a shell ¼ in thick. (See figures and formulas for hollow squares and rectangles, page 335.) $A = 6^2 - (5.5)^2 = 36 - 30.25 = 5.75$ sq in. $I = (bd^3 - b_1d_1^3)/12 = [6^4 - (5.5)^4]/12 = (1\,296 - 910)/12 = 386/12 = 32.2$. $r^2 = 32.2/5.75 = 5.6$ and $r = 2.37$ in.

The radii of gyration of round-section columns and square-section columns, ranging from 2 to 20 in in diameter and of metal varying from ¼ to 2 in thick, are given in Tables II and III, see pages 348 to 351. For example: the radius of gyration of a 6 by 6-in square-section cast-iron column with a shell ¼ in thick, is, from Table III, 2.35 in.

Graphical Method of Determining the Moment of Inertia of Plane Figures *

The Moment of Inertia may be Determined Graphically as follows: Divide the shape in question, Fig. 9,† into strips parallel to *BC*. Through the centers of gravity of the strips draw indefinite lines f_1, f_2, etc. Along a line *ab* lay off lengths f_1, f_2, etc., proportional respectively to the areas f_1, f_2, etc. When the strips are narrow and of equal width, each strip may be assumed proportional to the length of the strip measured through its center of gravity. Through *a* and *b* draw lines at 45° with *ab* to determine the pole *O*, from which the rays *Od*, *Oe*, etc., are drawn. Con-

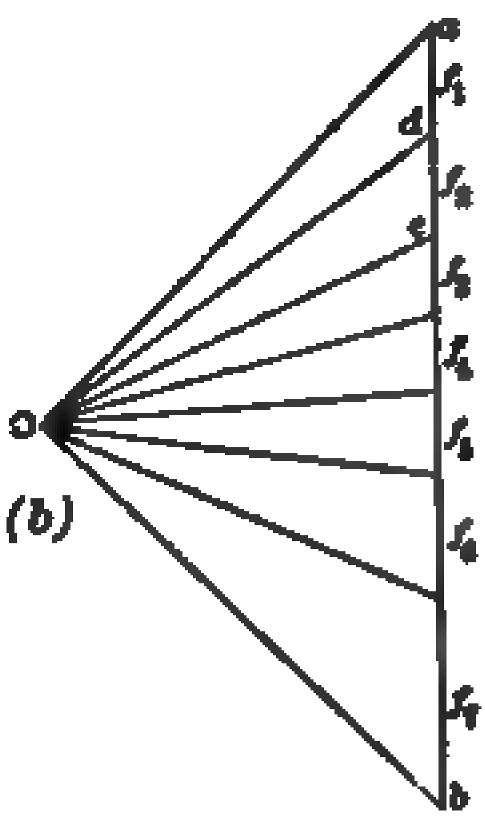

Fig. 9. Graphical Determination of Moments of Inertia†

struct the EQUILIBRIUM-POLYGON *gsf*. (See page 296.) A line *sS* parallel to *BC* will be a GRAVITY-AXIS. The MOMENT OF INERTIA about this axis is equal to the area of the given figure *ABC* multiplied by the area of the polygon *gsf*. The square root of this area *gsf* is the RADIUS OF GYRATION of the figure *ABC* with regard to the axis *sS*. A graphic method especially adopted to irregular figures is given in detail in Goodman's Mechanics Applied to Engineering. See, also, Merriman's American Civil Engineers' Handbook.

* From notes by Robins Fleming.
† Figure from Ott's Graphic Statics (Clark's Translation, London, 1876). See, also, ...'s Notes and Examples in Mechanics.

Table I.* Moments of Inertia of Rectangles

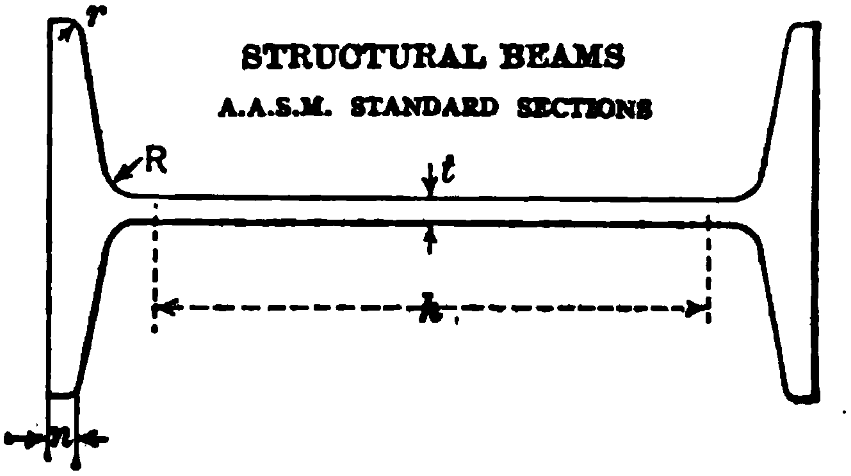
7. Dimensions, Moments of Inertia, Radii of Gyration and Sec Moduli of Standard Structural Shapes

Explanation of Tables. As in using structural-steel shapes the ch practically confined to such shapes as are rolled by the mills, it is essent have at hand the dimensions and properties of those shapes in order to late the necessary sizes to meet special requirements for strength and pr conditions of economy and framing. Since 1890 great changes have been both in the materials and in the shapes of the standard sections. The r mills which manufacture the most complete assortment of structural sha those of the Carnegie Steel Company, the Cambria Steel Company, the & Laughlin Steel Company and the Bethlehem Steel Company. In gener products of these mills, especially beams and channels, are respectively s in shape. This is particularly true of the shapes rolled by the first three companies named.

The standard steel beams and channels considered in the following pa rolled by all of these mills, with the exception of those of the Bethlehen Company. With a few exceptions the following tables of properties of ard structural shapes have been adopted by permission from the l Companion of the Carnegie Steel Company. It may be well to stat the tables of properties for the various structural shapes, published i companies named above, do not agree exactly, even for the same w but the differences are not of practical importance. The tables Cambria Steel Company and of the Carnegie Steel Company for bear channels agree more closely. As angles are very extensively used great many purposes, the properties are given for all sizes rolled and table showing from which mills the different sizes may be obtained. ally it will generally be advantageous to use a size that is rolled by mills.

Tables XV, XVI and XVII will be found very convenient when com the strength of struts formed of pairs of angles, and Table XVIII whe puting the same for pairs of channels.

Standard Steel Beams and Channels.* **Common Dimension**



n = minimum web = t

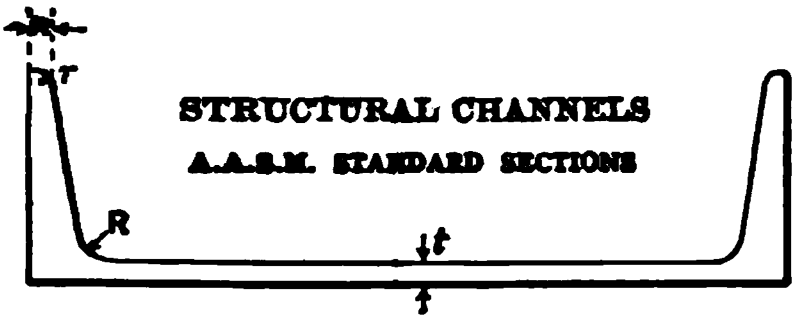
R = minimum web + 0.10″

r = 5/10 minimum web

h = distance between flange-fillets

Slope of flange, 1 : 6 = $16\frac{2}{3}\%$ = 9° 27′ 44″

* From Pocket Companion, Carnegie Steel Company, Pittsburgh, Pa.



n = minimum web = t

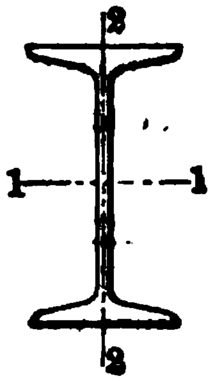
R = minimum web + 0.10″

r = $\frac{9}{10}$ minimum web

Slope of flange, 1 : 6 = $16\frac{2}{3}\%$ = 9° 27′ 44″

ensions for Structural Beams are those adopted by the Association of ican Steel Manufacturers and apply to all Structural Beams, except ican Standard Sections B 1, B 2 and B 3, also Sections B 24 and B 81. e dimensions of the Supplementary Beams, B 61 to B 68, inclusive, t be readily reduced to formulas. Slope of flange is 1 : 11 = 5° 11′ 40″. ensions for Structural Channels are those adopted by the Association erican Steel Manufacturers and apply to all Structural Channels, except s C 10, the 13-in sizes, which are Car Building Channels.

Table IV.* Properties of I-Beam Sections



Section-index	Depth of beam	Weight per foot	Area of section	Width of flange	Thickness of web	Axis 1-1			Axis 2-

* Rolled by the Jones & Laughlin Steel Company, Pittsburgh, Pa.

Table X. Sizes and Makes of Rolled Steel Angles

[illegible] following table has been compiled to show angles of various sizes rolled by [illegible] companies. The word "all" indicates that angles of the sizes mentioned are [illegible]d by all the companies included in the list. The abbreviations refer to the [illegible] companies: Cam., Cambria Steel Company; Car., Carnegie Steel Com[illegible]; J. & L., Jones & Laughlin Steel Company.

Angles with unequal legs		Angles with equal legs	
[illegible] in inches	Companies	Sizes in inches	Companies
8 ×6	Cam. and Car.	8 ×8	All
8 ×3½	Car.	6 ×6	All
7 ×3½	All	5 ×5	All
6 ×4	All	4½×4½	Cam.
6 ×3½	All	4 ×4	All
5 ×4	All	3½×3½	All
5 ×3½	All	3¼×3¼	J. & L.
5 ×3	All	3 ×3	All
4½×3	Car. and J. & L.	2¾×2¾	Cam. and J. & L.
4 ×3½	All	2½×2½	All
4 ×3	All	2¼×2¼	Cam. and J. & L.
3½×3	All	2 ×2	All
3½×2½	All	1¾×1¾	All
3½×2	J. & L.	1½×1½	All
3½×1½	J. & L.	1⅜×1⅜	J. & L.
3 ×2½	All	1¼×1¼	All
3 ×2	All	1³⁄₁₆×1³⁄₁₆	J. & L.
2½×2	All	1 ×1	All
2½×1¾	J. & L.	¾× ¾	J. & L.
2½×1½	Car. and J. & L.		
2½×1¼	Cam.		
2¼×1⅜	J. & L.		
2¼×1½	Car. and J. & L.		
2 ×1½	Car. and J. & L.		
2 ×1⅜	J. & L.		
2 ×1¼	Car.		
2 ×1	J. & L.		
[illegible]×1½	J. & L.		
[illegible]×1¼	Car.		
[illegible]×1⅛	J. & L.		
[illegible]×1¼	Car.		
[illegible]×1	J. & L.		
[illegible]× ⅞	J. & L.		
[illegible] ×¹³⁄₁₆	J. & L.		
[illegible] × ⅝	J. & L.

This table and the two following are employed in computing the safe resista compressive stress of two angles, back to back, used as struts or as the compre chords of roof-trusses, etc., by the following rule:

Obtain from the compression-formula in use the allowed stress per squar corresponding to the ratio of slenderness of the section, and multiply that val the area. The result will be the allowable compressive stress.

Example 1. Section given. Required the safe load in compression, as per fo $S = 19\,000 - 100\,l/r$, on a strut composed of two angles, 4 by 4 by ¼ in, back to with an unsupported length of 9 ft.

Area of section, $A = 3.88$ sq in; least radius of gyration, $r = 1.25$ in.

Ratio of slenderness, $l/r = 9 \times 12 \div 1.25 = 86.4$.

Allowed unit stress, $S = 19\,000 - 100 \times 86.4 = 10\,360$ lb per sq in.

Safe load, $AS = 3.88 \times 10\,360 = 40\,200$ lb.

Example 2. Stress given. Required a section for a member in compre 12 ft 3 in long, made of two angles separated by ½-in gusset-plates, to resist a stress of 35 000 lb; ratio of slenderness not to exceed 120.

Assume two angles, 5 by 3 by 5/16 in, long legs back to back.

Area of section, $A = 4.80$ sq in; least radius of gyration, $r = 1.26$ in.

Ratio of slenderness, $l/r = 12.25 \times 12 \div 1.26 = 116.7$.

Allowed unit stress, $S = 19\,000 - 100 \times 116.7 = 7\,330$ lb per sq in.

Safe load, $AS = 4.80 \times 7\,330 = 35\,200$ lb.

In the first case the least radius of gyration is that about the axis 1-1; in the s case, about the axis 2-2; in all cases the least radius of gyration determines th of slenderness and therewith the allowed safe compressive stress. In all cases the two angles are to be secured together by stay-rivets, so spaced as to insur the section acts as a unit. The ratio of slenderness of any single angle between must always be less than that of the strut or compression-chord.

CHAPTER XI

RESISTANCE TO TENSION. PROPERTIES OF IRON AND STEEL

By

HERMAN CLAUDE BERRY

PROFESSOR OF MATERIALS OF CONSTRUCTION, UNIVERSITY OF PENNSYLVANIA

1. Definitions, Working Stresses and Examples

The Ultimate Tensile Strength of a material is the amount of internal stress which a section one square inch in area is capable of exerting against an external axial force. It is the UNIT STRESS OR INTENSITY OF STRESS, expressed in pounds per square inch, which the material can withstand. It is often called the ULTIMATE STRENGTH OR ULTIMATE STRESS of the material. Its value for any material depends on the tenacity of the fibers or the cohesion of the particles of which the material is composed.

An Axial Force is one which acts uniformly over the section of a prismatic body so that the resultant of the distributed forces coincides with the axis of the body. Hence the total AXIAL FORCE which any cross-section of a body will resist is the product of the ultimate strength of the material and the area of the cross-section, in square inches.

Safe Working Stress. The ultimate strength of different building materials has been found by pulling apart bars of known dimensions and dividing the maximum load each sustained by the area of the bar before testing. This ultimate strength, however, must not be used to proportion the size of members in structures, because of variations in material, hidden defects and imperfect workmanship; and, especially, because of indefiniteness as to the maximum load that may be imposed on the structure. To provide safety against the rupture of a member and the consequent failure of the structure from any of these causes, the proportions of the members must be based on SAFE WORKING STRESSES which are usually some fractional part of the ultimate strength found by experiment to provide proper security against failure.

The Factor of Safety is the ratio of the ultimate strength to this safe working stress for that material. Its value ranges generally from 2 to 10, depending upon the nature of the material and the service to which it is applied.

Safe Working Stress in Tension. Table I gives these values for various building materials. The total SAFE LOAD that may be applied to a piece of material of uniform section is found by multiplying the cross-section of the piece, in square inches, by the safe working stress opposite the name of the material of which the piece is composed.

Then if P = the safe load in lb,

S_t = the allowable safe working stress in tension,

b = the width of a rectangular bar,

h = the depth of a rectangular bar,

d = the diameter of a round bar,

it results, for a rectangular bar,

$$P = bhS_t \tag{1}$$

for a round bar,

$$P = 0.7854\, d^2 S_t \tag{2}$$

The area of cross-section to support a load P is, for a rectangular bar,

$$A = \frac{P}{S_t}$$

and for a round bar

$$d = \sqrt{\frac{P}{0.7854\, S_t}}$$

Table I. Safe Working Stress in Tension for Building Materials *

Material	Safe stress lb per sq in (
Cast iron	3 000
Wrought iron	12 000
Steel, medium	16 000
Chestnut	850
Douglas fir	800
Hemlock	600
Pine. long-leaf yellow	1 200
Pine, short-leaf yellow	900
Pine, Norway	800
Pine, white	700
Redwood	700
Spruce	800
White oak	1 200

* **Note.** For woods these values may be increased up to 30% for selected, pe protected, commercially dry timber, not subject to impact, that is, for ideal cond (See, also, pages 637 and 647.)

Example 1. What size of medium-steel angle should be used to sust tensile force of 64 000 lb?

Answer. By Formula (3),

$$\text{the net sectional area} = \frac{64\,000}{16\,000} = 4.00 \text{ sq in}$$

From the Table of the Properties of Angles (Chapter X) we find that a 4 by ⅝-in angle has an area of 4.61 sq in, which is to be reduced by a ⅞-in for a ¾-in rivet, leaving $4.61 - (⅞ \times ⅝) = 4.06$ sq in, net area. This is sl in excess of the required amount.

The SAFE LOAD for angles commonly used in roof-trusses is given in Tal and the REDUCTION IN SECTIONAL AREA caused by rivet-holes, in Tabl this chapter, and in Table I, Chapter XX. See also, Chapter XII, pag paragraph on Punching Rivet-Holes.

Example 2. What size of white-pine tie-beam should be used to sus tensile force of 60 000 lb?

Answer. By Formula (3),

$$\text{the net sectional area} = \frac{60\,000}{700} = 85.7 \text{ sq in}$$

If the depth is taken at 12 in, the net width must be $\frac{85.7}{12} = 7.2$ in. Allo must be made for the increase in tension on the lower side of the beam, its own weight, and also for any cutting that may be necessary in maki connections or holes for truss-rods. If there is a 2-in hole through the b

by 12-in timber must be used. This makes allowance for the weight of the [illegible] itself. If the unsupported length of the beam is great, the allowance for [illegible] weight must be made according to the methods explained in Chapter XV, p. 572, for the calculation of tie-beams subjected to transverse loading.

2. Wrought Iron

Manufacture. Wrought iron is a mixture of pure iron and slag, about [illegible]% iron and 3% slag, together with from ½ to ¾% of other elements including [illegible], phosphorus, sulphur and manganese. It is made from pig iron and [illegible] oxide, or mill-scale, in a reverberatory furnace consisting of a firebox, a [illegible] or working-chamber, and the necessary dampers and flues. The impur[ities] are removed from the iron at different stages in the process, silicon and [man]ganese during the melting-down stage, part of the phosphorus and sulphur [dur]ing the clearing-stage and the carbon and remainder of the phosphorus and [sul]phur during the boiling-stage. The iron is then in a pasty condition ready [for] a thorough stirring by the workman, who collects it into balls of about 80 lb [we]ight and takes it to a squeezer or forge where the greater part of the slag is [remo]ved. It is then rolled out into MUCK-BARS. These bars are cut into pieces [whi]ch are piled into bundles suited to the size of the finished bar. The piles [are] heated and rolled again. The rolling reduces the amount of slag and makes [the] material denser. The process of rerolling may be repeated a number of [tim]es to produce double or triple-refined MERCHANT-BAR IRON.

The Appearance of Wrought Iron is very much like that of steel. It may [be] distinguished from steel by nicking one side of the bar and bending it away [from] the nick. Iron will split along the slag-laminations and show the COARSELY [fibro]us nature of the material; while steel will bend or rupture at the nick [with]out splitting, any fracture being FINELY FIBROUS or CRYSTALLINE. When [brok]en in a tension-test wrought iron shows a dark fibrous fracture. If the [speci]men is grooved before testing or broken in impact the fracture will be [part]ly crystalline.

Welds. Wrought iron is more easily welded than steel because the work [ma]y be accomplished through a wider range of temperature than with steel. [A we]ld may develop the full strength of the bar, but tests on hand-forged welds [thro]ugh tie-bars reported by Kirkaldy gave average values of about 60% of [the st]rength of the bar.

Use. Wrought iron is no longer used for the manufacture of structural [shap]es, such as angles, channels and beams, its use for structural work being [practi]cally limited to bars, rods and bolts. It can be worked more easily than [steel i]n threading-machines; and on this account, unless steel is specified, some [com]panies will furnish truss-rods, bolts, etc., in wrought iron.

Specifications * for Wrought Iron. Wrought iron may be purchased under [the] Specifications of the American Society for Testing Materials.

Material Covered. 1. These specifications cover two classes of wrought-iron [bar]s, as determined by the kind of material used in their manufacture, namely:

Class A, as defined in Section 2 (*b*);
Class B, as defined in Section 2 (*c*);

* [Th]ese Specifications for Wrought-Iron Plates are issued by the Society under the [des]ignation A 42. They were adopted in 1913 and revised in 1918. There are also [A.S.]T.M. Standard Specifications for Staybolt Iron, Refined Wrought-Iron Bars, Iron [an]d Chain, etc.

I. Manufacture

Process. 2. (*a*) All plates shall be rolled from piles entirely free from admixture of steel.

(*b*) Piles for Class A plates shall be made from puddle-bars made wholly pig iron and such scrap as emanates from rolling the plates.

(*c*) Piles for Class B plates shall be made from puddle-bars made wholly pig iron or from a mixture of pig iron and cast-iron scrap, together with wro iron scrap.

II. Physical Properties and Tests

Tension-tests. 3. (*a*) The plates shall conform to the following mini requirements as to tensile properties:

Properties considered	Class A		Class B	
	6 in to 24 in incl, in width	Over 24 in to 90 in incl, in width	6 in to 24 in incl, in width	Over : to 9 inc in wi
Tensile strength, lb per sq in	49 000	48 000	48 000	47 (
Yield-point, lb per sq in	26 000	26 000	26 000	26 (
Elongation in 8 in, per cent	16	12	14	1(

(*b*) The yield-point shall be determined by the drop of the beam of the te machine. The speed of the cross-head of the machine shall not exceed ¾ minute.

Modifications in Elongation. 4. For plates under $\frac{5}{16}$ in in thickn deduction of 1 from the percentages of elongation specified in Section 3 sh made for each decrease of $\frac{1}{16}$ in in thickness below $\frac{5}{16}$ in.

Bend Tests. 5. (*a*) COLD-BEND TESTS. The test-specimen shall cold through 90° without fracture on the outside of the bent portion, as fo For Class A plates, around a pin the diameter of which is equal to 1½ tim thickness of the specimen; and for Class B plates, around a pin the diame which is equal to three times the thickness of the specimen.

(*b*) NICK-BEND TESTS. The test-specimen, when nicked on one sid broken, shall show for Class A plates, a wholly fibrous fracture, and for C plates, not more than 10% of the fractured surface to be crystalline.

Test-specimens. 6. Tension and bend-test specimens shall be take the finished plates and shall be of the full thickness of plates as rolled. longitudinal axis of the specimen shall be parallel to the direction in whi plates are rolled.

Number of Tests. 7. (*a*) One tension, one cold-bend and one nic test shall be made for each variation in thickness of ⅛ in and not less th test for every ten plates as rolled.

(*b*) If any test-specimen fails to conform to the requirements specif reason of an apparent local defect, a retest shall be made. If the retest als the plates represented by such test will be rejected.

III. Finish

Finish. 8. The plates shall be straight, smooth, and free from cinde and holes, injurious flaws, buckles, blisters, seams, and laminations.

IV. Marking

Marking. 9. The plates shall be stamped or otherwise marked as designated the purchaser.

V. Inspection and Rejection

Inspection. 10. (*a*) The inspector representing the purchaser shall have entry, at all times while work on the contract of the purchaser is being per- ed, to all parts of the manufacturer's works which concern the manufacture the plates ordered. (See complete Specifications for Sections 10, 11 and 12.)

3. Cast Iron

Cast Iron has been defined as a saturated solution of carbon in iron, the on-content varying from 1½ to 4% according to the other impurities con- ed. It is hard, brittle, non-malleable and very fluid when melted, so that s well adapted for casting into complex forms.

Manufacture. It is produced in the blast-furnace, which is essentially a nd refractory-lined stack, with a valve-charging device at the top, tuyeres penings in the lower part for the introduction of the air-blast, and a hearth the bottom with a tap-hole for the periodic withdrawal of the iron and slag. e FURNACE-IRON is cast into PIGS about 3 ft long and weighing about 100 lb h. FOUNDRY-CASTINGS are made from PIG IRON and SCRAP melted in a cupola poured into green-sand molds. The charge is made up of different quanti- s of the different grades of pig so as to control the physical properties of the ings, principally through control of the silicon-content.

Appearance. CASTINGS have a gray or white fracture according to the condi- of the contained carbon, the gray fracture indicating graphitic or separated on and the white the combined carbon. GRAY IRON is softer and tougher is specified for ordinary CASTINGS.

Strength. Cast iron does not have a definite ELASTIC LIMIT. A relatively l stress will produce some permanent deformation. Its ULTIMATE TENSILE NGTH varies from 15 000 to 20 000 lb per sq in; and in some iron is as high 0 000 lb per sq in. Its COMPRESSIVE STRENGTH varies over a wide range, 00 lb per sq in being a fair average value.

Defects. Castings are liable to several common DEFECTS the chief of which blow-holes due to the formation of steam from the damp molds, sand-holes to misplaced sand, rough surfaces, cold shuts due to chilling of the iron failure to fill the parts of the mold, shrinkage-cracks due to uneven cooling e castings in parts of different thickness. In cored castings, also, the walls frequently of variable thickness because of the shifting of the cores. This is ially frequent in case of hollow columns cast in a horizontal position. use of these defects and on account of the low ULTIMATE STRENGTH, cast should never be used where it is subjected to any great tensile stress.

Specifications* for Cast Iron. The specifications of the American Society Testing Materials, for GRAY-IRON CASTINGS, include the following require- s:

Unless FURNACE-IRON is specified, all GRAY CASTINGS are understood to be by the CUPOLA-PROCESS.

The SULPHUR-CONTENTS are to be:

For light castings, not over 0.10 per cent.
For medium castings, not over 0.10 per cent.
For heavy castings, not over 0.12 per cent.

* These specifications are issued under the fixed designation A 48. They were adopted 5 and revised in 1918. The complete specification can be obtained from the Society.

3. In dividing castings into LIGHT, MEDIUM and HEAVY classes, the follo standards have been adopted:

Castings having any section less than ½ in thick shall be known as CASTINGS.

Castings in which no section is less than 2 inches thick shall be kno HEAVY CASTINGS.

MEDIUM CASTINGS are those not included in the above classification.

4. TRANSVERSE TEST. The minimum BREAKING STRENGTH of the TRATION-BAR under transverse load shall be:

For light castings, not under 2 500 lb.
For medium castings, not under 2 900 lb.
For heavy castings, not under 3 300 lb.

In no case shall the DEFLECTION be under 0.10 in.

TENSION-TEST. Where specified this shall be:

For light castings, not less than 18 000 lb per sq in.
For medium castings, not less than 21 000 lb per sq in.
For heavy castings, not less than 24 000 lb per sq in.

The specifications give explicit directions for casting the ARBITRATIO which is 1¼ in in diameter and 15 in long. Two of these are cast fo twenty tons of castings. One of each pair must fulfill the requirements t mit acceptance of the castings. The bar is loaded at the middle at a rat will cause a 0.10-in deflection in from twenty to forty seconds. The te test is not recommended.

11. CASTINGS shall be true to pattern, free from cracks, flaws and exc shrinkage. In other respects they shall conform to whatever points sl specially agreed upon.

4. Steel

Steel is a mixture of compounds of iron and carbon with small quant other elements, including manganese, phosphorus, sulphur, silicon, etc. carbon-content controls the hardness and strength of the steel. Les 0.10% of carbon is present in the soft steels, which have most of the teristics of wrought iron; while steel with more than 0.40% carbon is of being tempered, cannot be welded and is very much stronger. Mar acts as a cleanser during the process of manufacture, and increases the ab lity of the steel. Phosphorus and sulphur are harmful in their effects phorus making steel brittle under sudden loading and sulphur making it ho or brittle when heated.

Manufacture. STRUCTURAL STEEL is manufactured by the BESSEM the OPEN-HEARTH PROCESSES. In the first, molten cast iron is charged Bessemer converter, an air-blast is driven through the charge from perfo in the false bottom of the converter and the silicon, sulphur and carbon out. Carbon in the form of ferro-manganese is then added to deoxic charge and give the proper content of carbon in the finished steel, w quickly drawn off and poured into ingots. Phosphorus is not remove narily by the Bessemer process; but if the lining of the converter is basic material, such as dolomite limestone, and if lime is added with the the phosphorus will unite with it and be poured off with the slag.

The Open-Hearth Process. In this process scrap-steel, pig-iron or furnace-iron and limestone flux are charged on the hearth of a Siemens a reducing gas-flame is directed onto the charge and the carbon an impurities are gradually removed. When the reduction is about complet

are taken and carbon determined so that the charge may be withdrawn at the proper time. The process thus permits of much more accurate control of the product. The material is more uniform and consequently more dependable in service than BESSEMER STEEL. OPEN-HEARTH STEEL is used for most structural work.

Phosphorus may be removed by the basic process as in case of Bessemer steel. Ores running low in phosphorus are generally used in America so that the basic process is little employed here.

The Effect of Carbon and Phosphorus on the STATIC STRENGTH of steel within the limits of carbon included in structural steel is an increase in strength of about 1 000 lb per sq in for each 0.01% increase in either element. Cunningham's formula

$$S_t = 40\,000 + 100\,000\ (C + P)$$

is the approximate relation between the strength and the chemical composition. C and P are respectively the amounts of carbon and phosphorus expressed in percentage. For example, the ULTIMATE STRENGTH of a steel having 0.15% carbon and 0.07% phosphorus is, approximately,

$$S_t = 40\,000 + 100\,000\ (0.15 + 0.07) = 62\,000 \text{ lb per sq in}$$

The Percentage of Elongation decreases as the carbon-content and ULTIMATE STRENGTH increase. An approximate relation is

$$\text{percentage of elongation} = \frac{1\,400\,000}{S_t}$$

Since the TOTAL ELONGATION of a ruptured specimen is due to the local stretching at the point of rupture and the uniform elongation over the whole gauge-length, it is necessary to report the gauge-length when reporting this result. Since the LOCAL ELONGATION is the same for a 2 or an 8-in length, the PERCENTAGE OF ELONGATION for the same material, tested on a 2-in gauge-length, is greater than if measured on an 8-in length.

The Elastic Behavior of a specimen of steel loaded to rupture is best shown by a STRESS-STRAIN DIAGRAM on which the stresses are plotted as vertical ordinates and the elongations or strains as abscissas, as in Fig. 1. Five significant points are shown:

(1) **The Modulus of Elasticity** (E). The relation between the stress and the strain or elongation is called the MODULUS OF ELASTICITY. It is equal to the unit stress divided by the unit strain or deformation and is represented graphically by the tangent of the angle of the initial line with the horizontal. Its value for steel for tension is about 30 000 000 lb per sq in.

(2) **The Elastic Limit** ($E.L.$) is that unit stress beyond which the ratio of stress to strain ceases to be constant, or beyond which the curve ceases to be a straight line.

(3) **The Yield-Point** ($Y.P.$), slightly above or beyond the ELASTIC LIMIT, is the unit stress at which the specimen begins to stretch without increase in load. This stress may be determined from a test without the use of delicate measuring-apparatus by the DROP OF THE BEAM OF HALT IN THE GAUGE of the testing-machine.

(4) **The Ultimate Strength** ($U.S.$) is the greatest unit stress the specimen can sustain.

(5) **The Rupture-Stress** (R) is the unit stress at the time of failure. This is the unit stress at the point of failure after the area of the cross-section of the

specimen has been reduced; and because of the rapid dropping off of the l
it is difficult to determine. It is not regularly observed in testing, attent
being called to it merely to emphasize the fact that the ULTIMATE STRENGT
steel is not the stress at the time of failure of the specimen. This is true, a
for wrought iron and ductile materials in general.

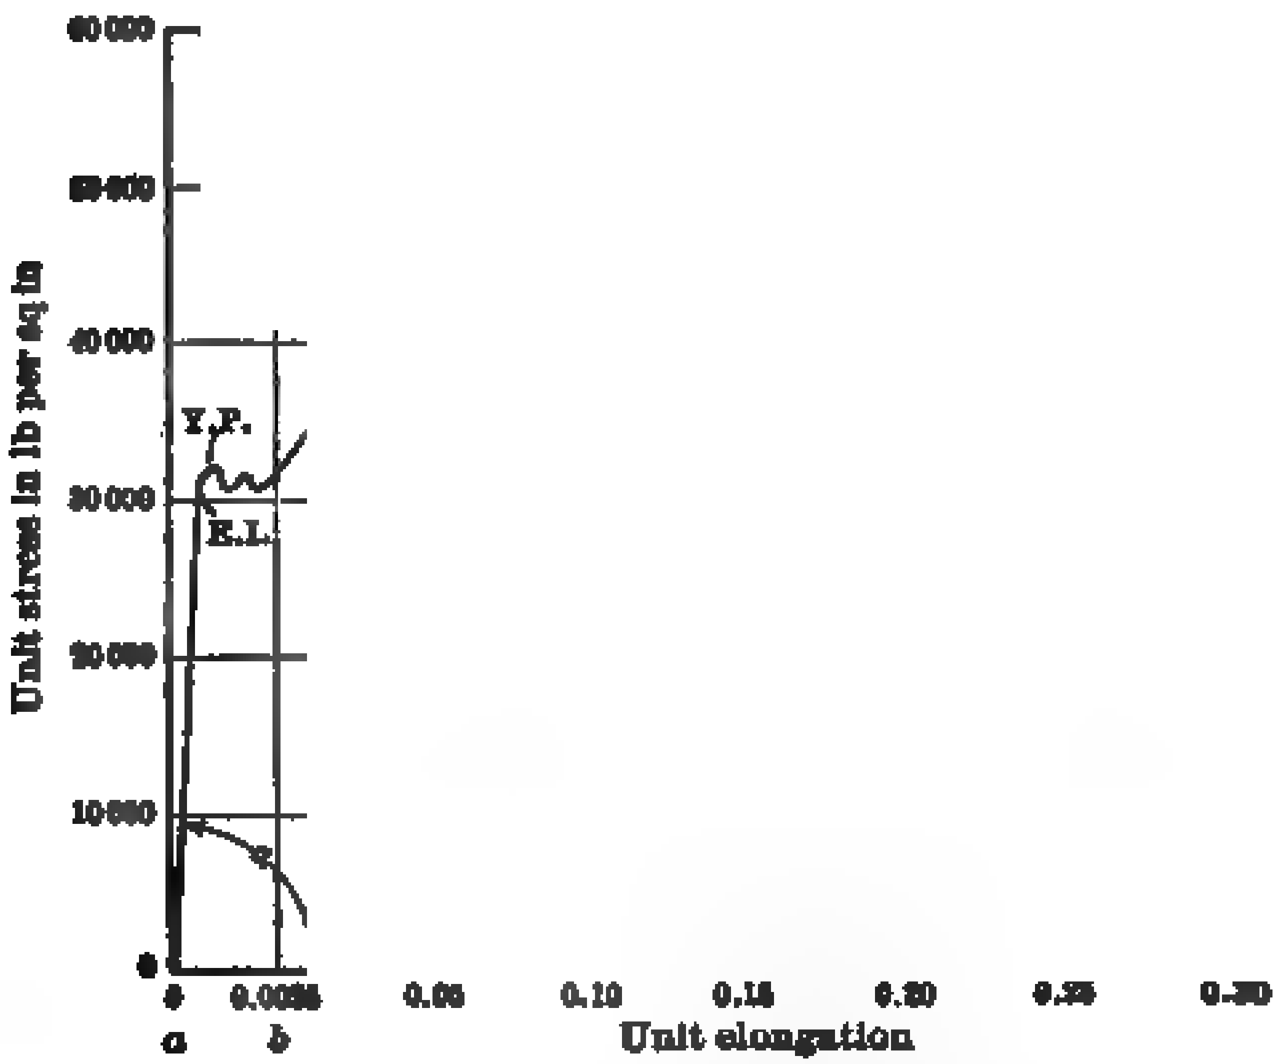

Fig. 1. Stress-strain Diagram of Test on Steel Specimens.

Effect of Punching and Shearing. Structural steel is hardened by
action of the punch and shear in the process of manufacture in the shop.
the die-side the metal is forced to flow from the tool and this cold wo
hardens and injures it as may be shown by a cold-bend test. The effect
be removed by annealing; but in the best work it is usually specified
rivet-holes shall be reamed during the assembling of the parts. This rem
the injured metal and brings the parts into better alinement for the ins
of the rivets. The injury from shearing may be removed by milling the sh
edges.

The Coefficient of Expansion of steel is 0.000 006 5 per degree Fahre
The ELONGATION in a length l, due to a change in temperature of t degr
then

$$e = 0.000\,006\,5\,lt$$

in which l is expressed in inches and t in degrees Fahrenheit.

The Weight of Steel is taken at 489.6 lb per cu ft. The sectional a
a member in square inches multiplied by 3.4 equals the weight in pounds
linear foot.

The Working Stress for structural steel in tension in buildings and bri

o lb per sq in in most specifications and building laws. For members ct to constant load some designers use a WORKING STRESS of 20 000 lb q in.

6. Standard Specifications for Structural Steel for Buildings

cifications. These specifications are issued by the American Society for g Materials under the fixed designation A 9. They were adopted in 1901 vised in 1909, 1913, 1914 and 1916. Extracts from these specifications :

I. Manufacture

cess. 1. (*a*) Structural steel, except as noted in Paragraph (*b*), may be by the Bessemer or the open-hearth process.

Rivet steel, and steel for plates or angles over ¾ in in thickness which are nched, shall be made by the open-hearth process.

II. Chemical Properties and Tests

mical Composition. 2. The steel shall conform to the following re- nts as to chemical composition:

Chemical content	Structural steel	Rivet steel
phorus { Bessemer......	not over 0.10 per cent	....
phorus { open-hearth....	not over 0.06 per cent	not over 0.06 per cent
hur..................	....	not over 0.045 per cent

le Analyses. 3. An analysis of each melt of steel shall be made by the cturer to determine the percentages of carbon, manganese, phosphorus lphur. This analysis shall be made from a test-ingot taken during the g of the melt. The chemical composition thus determined shall be re- l to the purchaser or his representative, and shall conform to the require- specified in Section 2.

ck Analyses. 4. Analyses may be made by the purchaser from finished al representing each melt. The phosphorus and sulphur-content thus ined shall not exceed that specified in Section 2 by more than 25 per cent.

III. Physical Properties and Tests

sion-Tests. 5. (*a*) The material shall conform to the following require- as to tensile properties:

Properties considered	Structural steel	Rivet steel
e strength, lb per sq in............	55 000–65 000	46 000–56 000
point, min, lb per sq in............	0.5 tens. strength	0.5 tens. strength
ation in 8 in, min, per cent.........	$\frac{1\,400\,000^*}{\text{tens. strength}}$	$\frac{1\,400\,000}{\text{tens. strength}}$
ation in 2 in, min, per cent.........	22	......

* See Section 6.

The yield-point shall be determined by the drop of the beam of the testing- e.

Modifications in Elongation. 6. (*a*) For structural steel over ¾ in in
ness, a deduction of 1 from the percentage of elongation in 8 in, specif
Section 5 (*a*), shall be made for each increase of ⅛ in in thickness above
to a minimum of 18 per cent.

(*b*) For structural steel under 5/16 in in thickness, a deduction of 2.5 fr
percentage of elongation in 8 in, specified in Section 5 (*a*), shall be made fo
decrease of 1/16 in in thickness below 5/16 in.

Bend Tests. 7. (*a*) The test-specimen for plates, shapes and bars, exc
specified in Paragraphs (*b*) and (*c*), shall bend cold through 180° without cr
on the outside of the bent portion, as follows: For material ¾ in or un
thickness, flat on itself; for material over ¾ in, to and including 1¼ in in
ness, around a pin the diameter of which is equal to the thickness of the spe
and for material over 1¼ in in thickness, around a pin the diameter of w
equal to twice the thickness of the specimen.

(*b*) The test-specimen for pins, rollers, and other bars, when prepa
specified in Section 8 (*e*), shall bend cold through 180° around a 1-in pin w
cracking on the outside of the bent portion.

(*c*) The test-specimen for rivet steel shall bend cold through 180° flat o
without cracking on the outside of the bent portion.

Test-Specimens. 8. (*a*) Tension and bend-specimens shall be take
rolled steel in the condi
which it comes from th
except as specified in
graph (*b*).

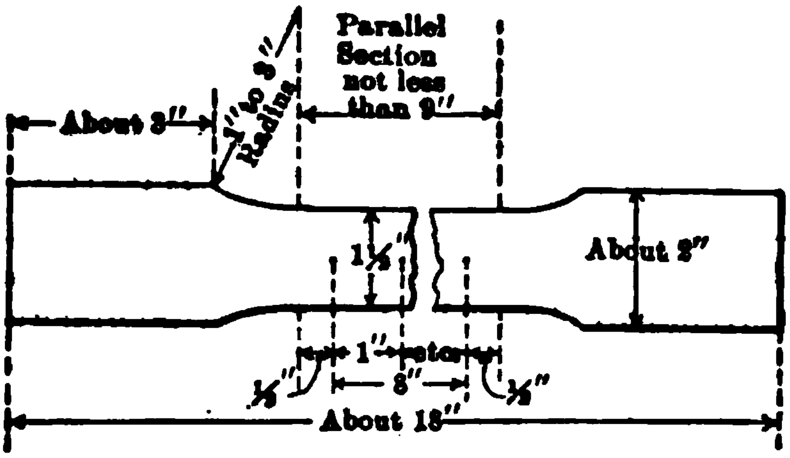

Fig. 1A. Form of Specimen for Steel-test

(*b*) Tension and be
specimens for pins and
shall be taken from t
ished bars after ann
when annealing is speci

(*c*) Tension and be
specimens for plates,
and bars, except as sp
in Paragraphs (*d*), (*e*
(*f*), shall be of the full thickness of the material as rolled; and s
machined to the form and dimensions shown in Fig. 1A, or with both
parallel.

(*d*) Tension and bend-test specimens for plates over 1½ in in thickness may be machined to a thickness or diameter of at least ¾ in for a length of at least 9 in.

(*e*) Tension-test specimens for pins, rollers and bars over 1½ in in thickness or diameter may conform to the dimensions shown in Fig. 2. In this case, the ends shall be of a form to fit the holders of the

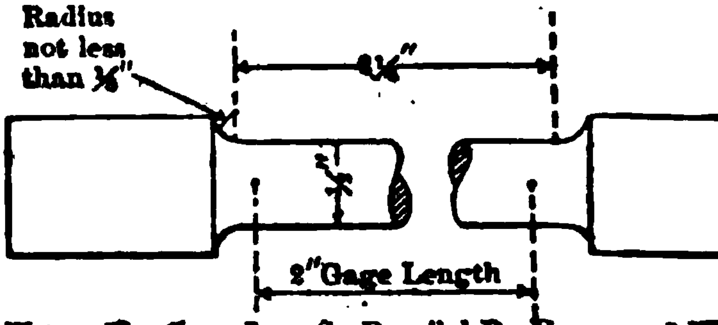

Fig. 2. Form of Specimen for Pins, Rollers,
etc., Over 1½ Inches Thick

testing-machine in such a way that the load shall be the axial. Bend-tes
mens may be 1 by ½ in in section. The axis of the specimen shall be lo
any point midway between the center and surface and shall be paralle
axis of the bar.

Tension and bend-test specimens for rivet steel shall be of the full-size n of bars as rolled.

mber of Tests. 9. (*a*) One tension and one bend-test shall be made from melt; except that if material from one melt differs ⅜ in or more in thickness, nsion and one bend-test shall be made for both the thickest and the st material rolled.

If any test-specimen shows defective machining or develops flaws, it may rded and another specimen substituted.

If the percentage of elongation of any tension-test specimen is less than ecified in Section 5 (*a*) and any part of the fracture is more than ¾ in the center of the gauge-length of a 2-in specimen or is outside the middle of the gauge-length of an 8-in specimen, as indicated by scribe-scratches ed on the specimen before testing, a retest shall be allowed.

IV. Permissible Variations in Weight and Thickness

rmissible Variations. 10. The cross-section or weight of each piece of steel not vary more than 2.5 per cent from that specified; except in case of ed plates, which shall be covered by the following permissible variations. ubic inch of rolled steel is assumed to weigh 0.2833 lb.

When Ordered to Weight per Square Foot: The weight of each lot in hipment shall not vary from the weight ordered more than the amount in Table I.*

When Ordered to Thickness: The thickness of each plate shall not more than 0.01 in under that order.

e overweight of each lot in each shipment shall not exceed the amount in Table II.*

V. Finish

ish. 11. The finished material shall be free from injurious defects and shall s workmanlike finish.

VI. Marking

rking. 12. The name or brand of the manufacturer and the melt-number be legibly stamped or rolled on all finished material, except that rivet and e-bars and other small sections shall, when loaded for shipment, be properly ted and marked for identification. The identification-marks shall be y stamped on the end of each pin and roller. The melt-number shall be y marked, by stamping if practical, on each test-specimen.

VII. Inspection and Rejection

pection. 13. (See complete Specifications for Sections 13, 14 and 15.)

6. Tension-Members

ges. The best section for tension-members of relatively small size depends y on the kind of end-connections used. Angles or channels are generally r riveted connections. For very small members rectangular bars, such as bars, may be used. The strength of such members is computed on the net hrough the rivet-holes. Angles used in tension should have lugs riveted e outstanding legs and the tie-plate for the better distribution of the stress the section. Tests on angles with riveted connections reported by F. Kibbent† gave from 77 to 86% of the strength of the material as shown by

* es I and II are omitted here for lack of space. The complete specifications can ined from the Society.

† ceedings of the American Society for Testing Materials, Vol. VI, 1906.

tension-tests on standard specimens cut from these angles. Lugs increase strength from 4.7 to 8.7%. It was also shown that a connection giving center of the pull on the center of gravity of the section gave considerably hi strengths than when the center of pull was in line with the gauge-line o rivets. In computing the NET SECTIONAL AREA as reduced by rivet and holes Table XI will be found very convenient.

Eye-Bars are used for the main tension-members of pin-connected tr They are rectangular in section with a forged head upset in dies and of the thickness as the bar. The eye is accurately drilled in position in the axis o bar, true to diameter and exact central distance. Because of its advan for forging, soft steel is used in making eye-bars. They are also carefully nealed before drilling. Table VI gives the dimensions of STANDARD EYE- manufactured by the mills of the American Bridge Company. These are of practically the same dimensions as the standard bars of other panies. There is from 34 to 42% excess material in the section through th to insure in the forged part the development of the full strength of the bo the bar. Standard bars should be used in design to avoid the expense of m special dies in which to form the heads. Bars of less than the given mini thickness are liable to fail, when loaded, by buckling in the head. Thick increase the BENDING-STRESSES in the pins and thus, indirectly, the nec size of the eye. Except for very large structures they are limited to 2 in.

Tests of Full-Size Eye-Bars are generally required when a great num them are to be used in a structure, one in every fifty bars being usually t The specifications for carbon-steel bars require that an ULTIMATE TE STRENGTH of 56 000 lb per sq in shall be developed, that the ELONGATION whole length shall be 10% and that failure shall occur in the body of th Nickel steel has been used for tension-members on a few long-span bridges. WORKING STRESS on the eye-bars was increased about one-half over that us

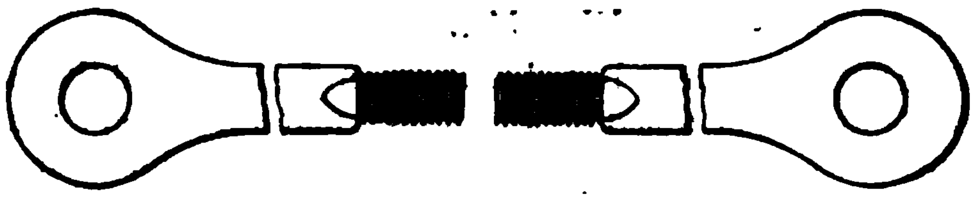

Fig. 3. Eye-bar with Screw-ends for Sleeve-nut or Turn-buckle

carbon steel, and the requirements of the test-bars made correspondingly The eye is made 1/50 in greater than the diameter of the pin. Bars pac the same pins are drilled at the same setting so as to be of exactly th length. Bars must be true to length within 1/32 in. Small eye-bars are times made with UPSET SCREW-ENDS and SLEEVE-NUTS or TURNBUCKLES middle for adjustment, as shown in Fig. 3 and Table VI, page 395.

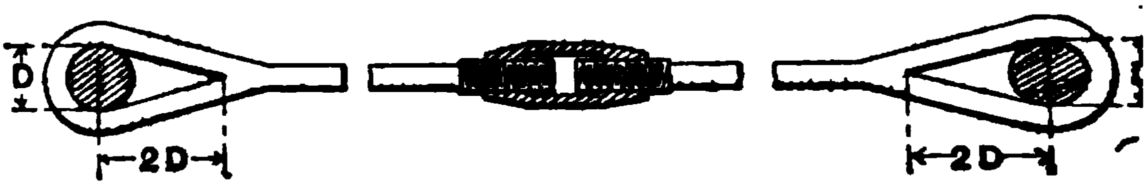

Fig. 4. Loop-eyes and Sleeve-nuts

Loop-Rods (Fig. 4, and Table VII) of round or square section with loop-ends are used for counterties and bracing. Because of the wel are not so dependable as other types of tension-members, but, because adjustment, are well adapted for this service as secondary members.

Forked-Loop Rod, Fig. 5, may be used for one of two tension-rods so as aid eccentricity where two rods balance each other on a pin. A CLEVIS ach end of one of the rods mplishes the same object.

mbuckles and Sleeve-Nuts. dimensions of these for adjust-ble lengths and initial stress in are given in Table VIII, page The open turnbuckle has the ntage of being easily inspected ite that the thread has sufficient ng and that the ends of the do not butt together.

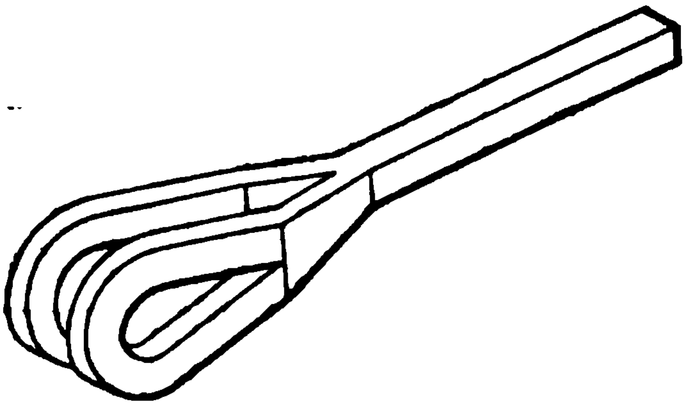

Fig. 5. Forked Loop

pset Screw-Ends are threaded enlargements on the ends of rods or bolts ed to give to the threaded portions a strength as great as that of the body e bar. Because of effects of forging it is necessary to make the area of the section of the upset end at the root of the thread a little larger than that e rod itself. A standard upset rod will fail in the body of the bar with-amaging the threaded portion enough to prevent the turning of the nuts. dimensions given are nearly the same with all manufacturers. If upset can not be obtained the section-area at the root of the thread must be in computing the safe load.

evises. Table IX, page 398, gives the dimensions and other details for es according to the latest standards of the American Bridge Company.

bles. The following tables will be found useful in designing tension-bers, or for drawing turnbuckles, sleeve-nuts, clevises, etc. The strength in rods in Table II is based on the area at the root of the thread. For s and weights of tie-rods and anchors for steel beams, see Table XIX, ter XV.

REMARKS. As upsetting reduces the strength of iron, bars having the same dia at the root of the thread as that of the bar invariably break in the screw-end tested to destruction, without developing the full strength of the bar. It is the necessary to make up for this loss in strength by an excess of metal in the upset s ends over that in the bar.

Table V is the result of numerous tests on finished bars made at the Keystone B Company's Works in Pittsburgh, Pa., and gives proportions that will cause the b break in the body rather than in the upset end.

The screw-threads in the above table are the Franklin Institute standards.

To make one upset end for a 5-in length of thread, allow 6 in in length of rod, tional.

½	41 000	5/16	16 600
⅜	31 500	¼	13 400

*These are special angles. It is better not to use them in ordinary work because of t of delay in delivery.

he End-Connections often determine the strength of ANGLE TENSION-MBERS. Some specifications for structural work require angles subject to ct tension to be connected by both legs if the section of both legs is conred; and if connected by one leg, the section of one leg only is considered ective. Reliable tests (page 385) show this requirement to be needlessly re. For single angles connected by one leg, the Specifications for the ctural Steelwork of Buildings, Chapter XXX, allow the net area of the nected leg and one-half that of the outstanding leg to be considered effective. e Waterbury, Stresses in Structural Steel Angles, John Wiley & Sons, Inc., w York, 1917.)

Table XI. Sectional Area to be Deducted from Plates and Angles for One Round Hole

Note. Bolt-holes should be 1/16 in larger than the diameter of the bolt; rivet-h are usually 1/8 in larger than the diameter of the rivet.*

* See also Table I, Chapter XX and paragraph, Punching Rivet-Holes, page 414.

7. Wire

Manufacture. Iron and steel wires are made from BILLETS about 4 in squa These are rolled into long rods which are dipped in acid to remove the sc and furnish lubrication for the drawing process. This consists in pulling rods while cold through steel dies having a series of holes of gradually decreas diameters. The cold working of the metal hardens it and makes it brittle that it is necessary to anneal it at intervals during the process. The draw increases the strength of the material, so that wires of different sizes, altho made of the same material, differ greatly in ULTIMATE STRENGTH.

Finish. The common grades of iron and steel wire are furnished in sev different finishes: plain black, bright tinned, copper-coated, japanned and w single and double coats of zinc galvanizing. The last is applied by passing wire through the melted zinc which is deposited as a coating and forms on the best-known protections against corrosion.

Wire-Gauges. Table XIII gives, according to several GAUGES, the diame of the different numbers of wire that have come into use for different purp and have been brought out by different manufacturers. In ordering wire number it is best to specify which GAUGE is meant.

Strength. Table XIV gives the sizes according to the J. A. Roebling's S Company gauge, with the weight and length and the strength on an assum basis of 100 000 lb per sq in. The different kinds of wire vary so widely in u MATE STRENGTH, on account of both the difference in quality of the material the effect of the drawing, that in order to obtain the approximate strength

e, reference must be made to Table XII in connection with the foot-note to ble XIV. The following table is arranged from values which were published the Catalogue of the J. A. Roebling's Sons Company:

Table XIII. Approximate Ultimate Strength of Different Sizes of Iron and Steel Wire

Kind of wire	Ultimate strength	
	Large size lb per sq in	Small size lb per sq in
t iron	45 000	60 000
legraph and telephone (steel)	60 000	80 000
cial aviator	247 000	285 000
no wire	307 000	340 000
ugh steel wire	200 000	345 000
rd-drawn copper trolley wire	50 000	not used
rd-drawn telegraph and telephone copper	56 000	66 000

The Uses of Wire are so many and varied that a bulky treatise would equired to adequately cover the subject. The catalogues of the American el and Wire Company mention electrical wires and cables of many kinds, phone and telegraph wires, ignition-wires and cables for automobiles, motor-ts and aeroplanes, wire rope, wire tacks, wire fences, piano-wire, barbed e, flat wire and so on, through a long list. The magnitude of the wire-output the United States is seen from the fact that of the total production of 32 000 000 s of all kinds of finished rolled iron and steel for the year 1916, 3 500 000 tons e wire rods. For electrical purposes copper wire is mostly used. See ctric Work for Buildings, Part III, for information regarding wires and wire-ulations.

The Brown & Sharpe Gauge is followed in the United States as the ndard for copper wire, though there is a growing tendency to distinguish ent electrical wires by their diameters, expressed in mils. (One mil = in. A circular mil is the area of a circle 0.001 in in diameter.)

The American Steel and Wire Company's Gauge is almost universally used throughout the United States for steel wire. The Birmingham gauge, English gauge, is the only wire-gauge recognized in successive Acts of gress establishing tariffs, and for many years has been used as the basis duties assessed on imported wire. Aside from these purposes its use is not nsive. The American Steel and Wire Company's Music-Wire-Gauge, known as the Music-Wire-Gauge, upon recommendation of the United tes Bureau of Standards, has been adopted as the standard for piano-wire.

* See, also, pages 402, 403, 1469, 1473, 1509, 1510, 1512, and 1600.

...is table was calculated on a basis of 483.84 lb per cu ft for steel wire. Iron wire is ...le lighter.

...e breaking strengths were calculated for 100 000 lb per sq in throughout, simply ...venience, so that the breaking strengths per square inch of wires of any strength ...be quickly determined by multiplying the values given in the table by the ratio ...en the strength per square inch and 100 000. Thus, a No. 15 wire, with a strength ...square inch of 150 000 pounds, has a breaking strength of

$$407 \times \frac{150\,000}{100\,000} = 610.5 \text{ lb.}$$

...must not be inferred from this table that steel wire invariably has a strength of ...00 lb per sq in. As a matter of fact its strength ranges from 45 000 lb per sq in for ...annealed wire to over 400 000 lb per sq in for hard wire.

† Also American Steel & Wire Company, etc.

8. Wire Rope

Kinds of Wire Rope. There are several kinds of WIRE ROPE in com use. In each there are three or more qualities depending on the kind of used and the kind of core about which the strands are laid. The Trenton Company lists the following:

(1) **Haulage or Transmission-Rope,** composed of six strands of seven each, laid about a hemp core. It is used for haulage, transmission of powe places where surface-wear is of chief consideration and where sheaves of suffi diameter may be used.

(2) **Hoisting-Rope,** composed of six strands of nineteen wires each. used for elevator service, shafts and derricks, and in places where it is not ject to abrasion and where flexibility is of chief consideration.

(3) **Seale Rope,** composed of six strands of nineteen wires each, the coils of the strands being of finer wire. It is intermediate in flexibility bet the first and second kinds of rope.

(4) **Non-Spinning Hoisting-Rope,** having eighteen strands of seven wires Twelve of the strands are laid in reverse direction to the inner six, ma it well adapted for hoisting in free suspension without untwisting and tur the load.

(5) **Extra-Flexible Hoisting-Rope,** having eight strands of nineteen wires

(6) **Special Flexible Hoisting-Rope,** having six strands of thirty-seven each.

(7) **Hawser-Rope and Flexible Running-Rope,** having six strands of t galvanized wires each, laid about a hemp core.

(8) **Tiller-Rope,** composed of six small seven-strand ropes laid about a core. It is the most flexible of wire ropes and is used to operate tillers an hand-ropes in elevators.

The Lay of Wire Rope is the twist of the wires in the strands relativ the strands in the rope. In the ORDINARY LAY the twist of the strands reverse of that of the wires, while in the LANG LAY the strands are laid i same direction as the twist of the wires. This latter gives a greater distrib of the wearing-surface and a somewhat greater flexibility; but it has th advantage of a tendency to untwist and for this reason should not be use hoisting weights in free suspension. Wire rope is also made up in FLAT O BON FORM. For large sizes it is more flexible than standard rope and m run over smaller drums.

Materials for Rope. Nearly all of the above kinds of rope are made the following materials:

(1) **Best Grade of Wrought Iron.** This is used in high-speed PASSE ELEVATOR SERVICE as it seems to suffer less from the effects of the stresse to the starting and stopping of the cars.

(2) **Cast-Steel Wire,** with an ultimate strength of from 160 000 to 210 c per sq in, according to the size used.

(3) **Extra-Strong Cast-Steel Wire,** with an ultimate strength of from 19 to 230 000 lb per sq in.

(4) **Plow-Steel Wire** with an ultimate strength of from 200 000 to 230 per sq in.

Ordinary GALVANIZED-WIRE ROPE should not be used for other than sta rope. A short service running through sheaves will break the coating and

Table XV. Strength of Wire Rope

Arranged from the 1912 list of John A. Roebling's Sons Company

Trade number	Diameter inches	Weight per foot, hemp core	Approximate breaking-load in pounds		Minimum diameter of drum or sheave in feet

e working load is to be taken at one-fifth the breaking-load. This is assumed i
lating the diameter of the sheaves.

rapid corrosion of the rope. Because of the many kinds and qualities of r
it is well to consult the manufacturers as to which kind will best suit the co
tions for any particular service. The John A. Roebling's Sons Company, T
ton, N. J., the Trenton Iron Company, Trenton, N. J., and A. Leschen & S
Rope Company, St. Louis, Mo., are among the largest manufacturers of
lines of ropes.

Coils. Wire rope should not be coiled like hemp rope, and in order to a
kinking, should be taken from the reels without twisting. If it is not shippe
a reel, to avoid injury it must be rolled over the ground like a wheel.

Lubrication. It is very important that running ropes be properly lu
cated, since, if proper care is not taken, the wear on the interior parts, betw
the wires, may be almost as great as the outside abrasion. The oil should p
trate to the core of the rope and yet not drip off a few days after applica
Information as to the care of rope may be obtained of the Wire Rope Lub
ting Company, Newark, N. J.

Sheaves. The size of sheaves recommended in the tables are calculated
a working-load of one-fifth the given breaking-load. If smaller sheaves are
the life of the rope will be greatly shortened, because of the excessive ben
of the outer wires.

Table XVI. Galvanized, Steel-Wire Strands

For guys, signal-cords, trolley-line span wire, etc. Taken from the American Steel & Iron Company's list

Diameter in inches	List price per 100 feet *	Weight per 100 feet	Approximate breaking-load in pounds
5/8	$7.25	80	14 000
9/16	5.75	65	11 000

1/8	1.00	3¼	600
3/32	.80	2	400

9. Cotton, Hemp and Manila Rope

Rope is made of cotton, hemp, and Manila fiber. Cotton is used for
sizes, only, and for such purposes as sash-cord, etc.

Manufacture. In the manufacture of rope the fiber is first spun into
From twenty to eighty threads are twisted together into STRANDS an
strands, three or four, are laid together, opposite in direction to the TW
the strands, but in the same direction as the THREADS. This causes the
to be twisted as the rope untwists and produces a balancing of forces tha
to keep the rope in shape.

Cables and Hawsers are made up of strands of rope.

* These pre-war prices must be increased as per current price-lists.

pe used for Hoisting wears rapidly from the action of the pulleys and from the bending which causes a slight internal motion between the fiber a chafing and grinding away of the interior.

tevedore-Rope, of the C. W. Hunt Company, is filled with a tallow and ago lubricant which decreases the internal friction, lubricates the outside e rope and thus greatly prolongs its life.

rength. The values of the strength of new rope, given in Table XVII, are n from the Specifications of the United States Navy Department, issued ne, 1910, at the Boston Navy-Yard. Manufacturers generally adopt these and weights and claim a strength equal to or a little greater than the values a. The UNIT STRENGTH for the different sizes varies, being about 14 000 lb q in for the smaller and about 10 000 for the largest size. The approx e formula, offered by C. W. Hunt, of 720 times the square of the circum ce in inches, is equivalent to about 9 000 lb per sq in. American hemp d, has about 5% greater strength than Manila rope of the same size. The specifications give for two-strand American-hemp rope, 85% of the strength e three-strand rope of the same material.

Table XVII. Strength and Weight of Rope

Specifications of the United States Navy, June, 1910

Circum-ferences in	Diameters in	Manila hemp, plain-laid: Weights lb per ft	Manila hemp, plain-laid: Breaking-loads lb	American hemp, tarred, plain-laid, three strands: Weights lb per ft	American hemp, tarred, plain-laid, three strands: Breaking-loads lb

3	0.95	0.305	7 800	0.37	8 400
3 1/4	1.03	0.36	9 200	0.44	9 800
3 1/2	1.16	0.42	10 500	0.51	11 200
3 3/4	1.19	0.47	12 200	0.59	13 000
4	1.27	0.54	13 700	0.67	14 550
4 1/2	1.43	0.67	17 400	....	......
5	1.59	0.83	21 800	....	......
5 1/2	1.75	1.00	27 700	....	......
6	1.90	1.21	31 000	....	......
7	2.22	1.63	36 200	....	......
8	2.54	2.17	47 300	....	......
9	2.87	2.70	60 000	....	......
10	3.14	3.33	74 200	....	......

ila-hemp rope is made in three strands and in sizes up to 3 in in circumference ands are used for sizes larger than 3 in in circumference.

Working Load. The WORKING LOAD for slow-speed derrick and hoi service is usually taken at one-seventh the BREAKING-LOAD. This makes allowance for the loss of strength at splices and connections. The deterio of rope exposed to the weather is very rapid. For Manila rope from 1 to in diameter, running over sheaves of the diameters given, C. W. Hunt in T Am. Soc. M. E., Vol. XXIII, gives a table embodying approximately th lowing results of experience:

Table XVIII. Working Loads for Manila Rope

Working load = C × breaking-load of new rope

D = minimum diameter of sheave in inches

Speed	Feet per minute	Kind of work	Value of C	D for rop diamete 1 in	1
Slow......	50 to 100	Derrick, crane, quarry, etc.	0.014	8	
Medium...	150 to 300	Wharf, cargo, etc.	0.056	12	
Rapid.....	400 to 800	....	0.028	40	

The wear in such service is very rapid, a 1½-in rope wearing out in liftin 7 000 to 10 000 tons of coal. On the other hand, a 1½-in transmissio running at 5 000 ft per min and carrying 1 000 horse-power over sheave and 17 ft in diameter, lasts for years, the difference being due to the s stress and larger sheaves.

10. Chains

Manufacture. Large chains are made by hand-welding from best wr iron bar, and small chains up to ½ in are best made of mild open-hearth electric-welded. The bending and welding reduce the strength so th chain is not twice but only from 1.55 to 1.70 times as strong as the origin from which it was made. STUD CHAIN having a bar welded across eac to stiffen it and prevent fouling in handling, is not as strong as OPE CHAIN, but has a higher elastic limit and working strength. G. A. Goode in a Bulletin from the Illinois Engineering Experiment-Station, finds the mum stresses at the elastic limit of the material to be as follows: If P load, d the diameter of the bar, and S the stress, the formulas are:

$$P = 0.5\, d^2S \text{ for stud-link, and}$$
$$P = 0.4\, d^2S \text{ for open link.}$$

Proof-Tests. A proof-test is applied to chains by the manufacturers load applied is one-half the average BREAKING-LOAD. It serves to dete welds and gives a chain a slight permanent set, so that for working loads after there will be little stretching of the chain.

Care of Chains. Chains in constant use require lubrication and fr annealing. They harden in service and are liable to unexpected failure annealed. It is recommended that hoisting chains and sling chains be an at least once a year.

Table XIX. Sizes, Weights, Proof-Tests and Average Breaking-Loads for Chains

Bradlee and Company, Philadelphia

Size of chains in	Approximate weight per foot	D.B.G. special crane Proof-test lb	D.B.G. special crane Average breaking-load lb	Crane Proof-test lb	Crane Average breaking-load lb
1/4	3/4	1 932	3 864	1 680	3 360

1 7/8	121 937	212 188	3 1/8	339 102	567 823

Factors of Safety. For dead loads the FACTOR OF SAFETY may be a as four provided the breaking of the chain would not imperil life. This factor generally quoted in catalogues, but is too low for most purposes MAXIMUM FIBER-STRESS is then well above the ELASTIC LIMIT of chain Where loads are to be raised repeatedly with machinery which can be op without jerks or sudden change of speed, the use of a factor of six is practice. If a chain must be used where shocks occur, the INSTANTA LOAD should be calculated, and a high factor of safety employed.

Grades of Chain. Chains up to 1 ¼ in are usually made in three g called PROOF, BB, and BBB. The proof is the cheapest grade, and is m longer links than the others. This is not ordinarily proof-tested. BB next grade, somewhat shorter linked, and is proof-tested. BBB is shorter link and more carefully made.

Crane Chain is finished in such a way as to be without twist when h with one end free, so that hooks and fittings are always facing their direction.

Dredge Chain is straightened as is Crane Chain, and made with u links to run over a wheel.

Steel Loading Chain is made mostly in small sizes for use where the compared to the strength is to be a maximum. It is the highes hand-made chain.

Block Chain is fitted to the pocket-wheel in which it is to run. In sizes it is usually electric-welded.

Electric-Welded Chain is made in small sizes and is rapidly replaci hand-made below ½ in. It is stronger and more uniform.

Sizes of Chain. Chain is ordinarily made of wire or rod, 1/32 in large the NOMINAL DIAMETER, by which it is called. If chain is desired made of the size by which it is called, it must be specified as EXACT SIZE. Steel I Chain, Block Chain, and frequently Dredge Chain, are made EXACT. Link Anchor Chain is made of wire, 3/64 in above its NOMINAL DIAMETER

CHAPTER XII

RESISTANCE TO SHEAR. RIVETED JOINTS. PINS AND BOLTS

By
HERMAN CLAUDE BERRY
PROFESSOR OF MATERIALS OF CONSTRUCTION, UNIVERSITY OF PENNSYLVANIA

1. Shear

Shear is the internal stress in a body which resists the tendency of two adjacent parts to slide on each other, due to the action of two equal and parallel external forces, called SHEARING-FORCES, acting on opposite sides of the plane of shear.

If the piece *abcd* of Fig. 1 represents a short simple beam of brittle material on which a sufficient load is applied, it will fail in VERTICAL SHEAR at *f* and *g*, as shown, by a sliding on the sections of the beam at these points, because the upward force of the reaction at *S* and the downward force of the load adjacent to *S*, against which it acts across the section at *S*, is greater than the total SHEARING RESISTANCE of the section.

Fig. 1. Shearing-failure of Beam

Shear is present over the entire length of the beam, and at any section is equal to the reaction at *S* minus the weight of the load between the reaction and the section in question. In general, the VERTICAL SHEAR at any section of a beam subjected to vertical loads is equal to the algebraic sum of all the vertical forces acting on the beam on either side of the section.

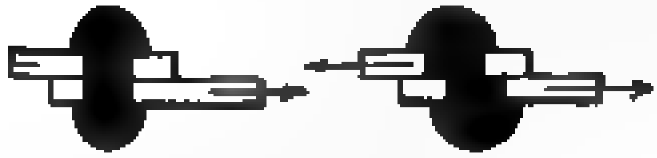

Fig. 2. Example of Single Shear

Single and Double Shear. A rivet connecting two bars under tension (Fig. 2) is subjected to a SHEARING-STRESS. If one section of the rivet transmits the force the rivet is said to be in SINGLE SHEAR; if two sections, it is in DOUBLE SHEAR.

Distribution of Shear. Shear is considered to be UNIFORMLY DISTRIBUTED over the section except in cases of torsion and of complex stresses.

For the ordinary cases of shear in rivets, etc., if

S_s = the allowable unit stress in shear,
A = the area under stress,
P = the safe shearing-load;

$$P = AS_s \qquad (1)$$

The Ultimate Strength in Shear has been determined for building materials by testing suitably prepared specimens and dividing the maximum load ob-

served by the area under stress. For material like wood, in which there planes of weakness, tests must be made which take these into account. direction of the force with respect to these planes must be considered in ch ing the SAFE WORKING STRESS from the tables.

Safe Working Stresses in Shear. Table I gives SAFE WORKING STRES in SHEAR for those building materials usually subjected to such stresses.

Table I. Safe Working Stress in Shear for Building Materials*

Material	Safe stress in lb per sq in	
Cast iron (New York)	3 000	
Wrought iron	7 500	
Steel, bolts, rivets	10 000 (average)	
	With the grain	Across th grain
White oak	200	1 000
White pine	100	500
Long-leaf yellow pine	150	1 250
Short-leaf yellow pine	130	1 000
Douglas fir	100	900
Hemlock	100	600
Spruce	100	750

* Note. For woods, these values may be increased up to 30% for selected, pert protected, commercially dry timber, not subject to impact, that is, for ideal condi (See, also, pages 637 and 647.)

Shear in Wooden Tie-Beams. There are a few cases in architectural struction in which the weakness of wood in shear must be provided for. one most frequently arising i framing of the end of the beams in wooden trusses.

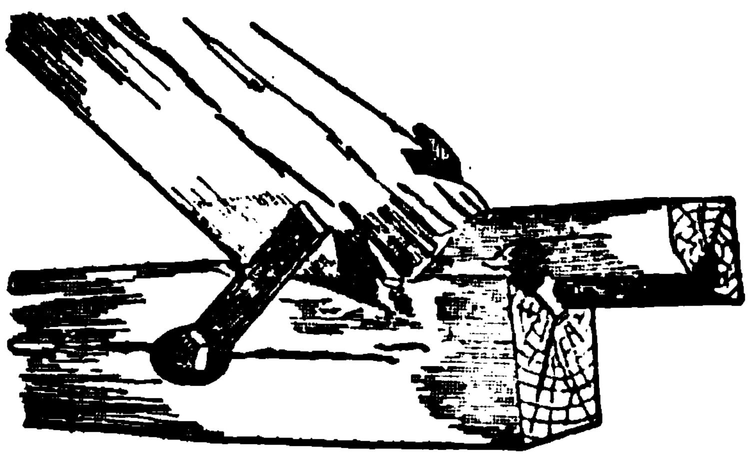

Fig. 3. Shearing-failure in Wood

Fig. 3 was made fro photograph of a SHEAI FAILURE of a tie-beam from thrust of the rafter.

Horizontal Shear Wooden Beams. Failure that shown in Fig. 1 r occurs in wood; but rectan wooden beams, the lengt which is less than about twenty times the depth, are liable to fa HORIZONTAL SHEAR along the middle, under about the same loads that the allowable working stresses in bending.

Shear at the End of a Tie-Beam. In the case of the truss-joint (Fi the thrust S of the rafter tends to shear off the part $ABCD$ along the pla which CD is the trace. This area under stress must offer a SHEARING RE ANCE equal to the horizontal component H of the thrust S. The width beam b, being fixed, formula (1) gives

$$H = (CD \times b)S_s \quad \text{or} \quad CD = H/bS_s$$

The shear being in the same direction as the grain of the wood, the lower in Table I must be used.

Example 1 (Fig. 4). The horizontal component of the thrust of a rafter is 20 000 lb. The long-leaf yellow pine tie-beam is 10 in wide. How far should the beam extend beyond the point D?

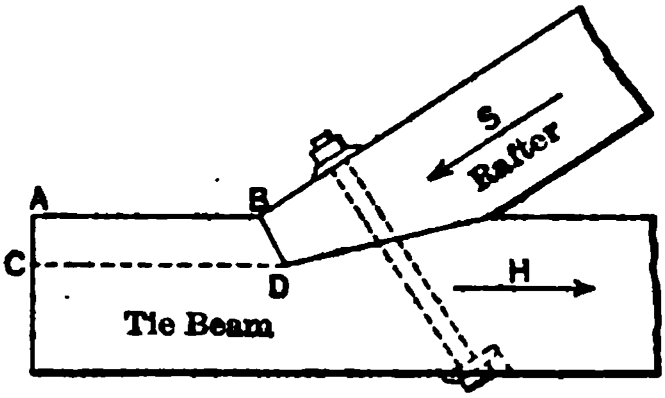

Fig. 4. Truss-joint

Solution. In this case $H = 20\,000$ lb. From Table I, $S_s = 150$ lb per sq in. Then $CD = \dfrac{20\,000}{10 \times 150} = 13.3$ in and should be made at least $13\frac{1}{2}$ in.

As actually constructed a large part of the thrust is generally taken by a bolt or strap at the foot of the rafter to hold it in place. As the bolt and shoulder seldom act together, either the length CD on the tie-beam should be made long enough to resist the entire thrust, or the bolt or strap designed to do so without relying on the shearing resistance in the plane of CD. The design of such joints is more fully considered under Subdivision 4, pages [4]39 to 439 of this chapter.

2. Riveted Joints

Use of Rivets. Rivets almost exclusively are used in connecting the plates and shapes which make up the members of framed steel construction.

Rivet-Definitions. A rivet is a piece of cylindrical rod with a HEAD forged on one end and usually with a slight taper at the other end of the SHANK. The GRIP (Table IV) of the rivet is the length betweeen the under sides of the heads after driving, or the thickness of the parts joined. The LENGTH (Table IV) of the rivet is equal to the grip plus enough of the stock to form a head, and is measured from the end of the shank to the under surface of the head. The DIAMETER OF THE SHANK of a rivet is made equal to its NOMINAL DIAMETER, but rivets are driven into holes $\frac{1}{16}$ in larger in diameter and upset by the driving so as to completely fill the holes. The shearing values and bearing values are based upon the NOMINAL AREA and not upon the area of the hole.

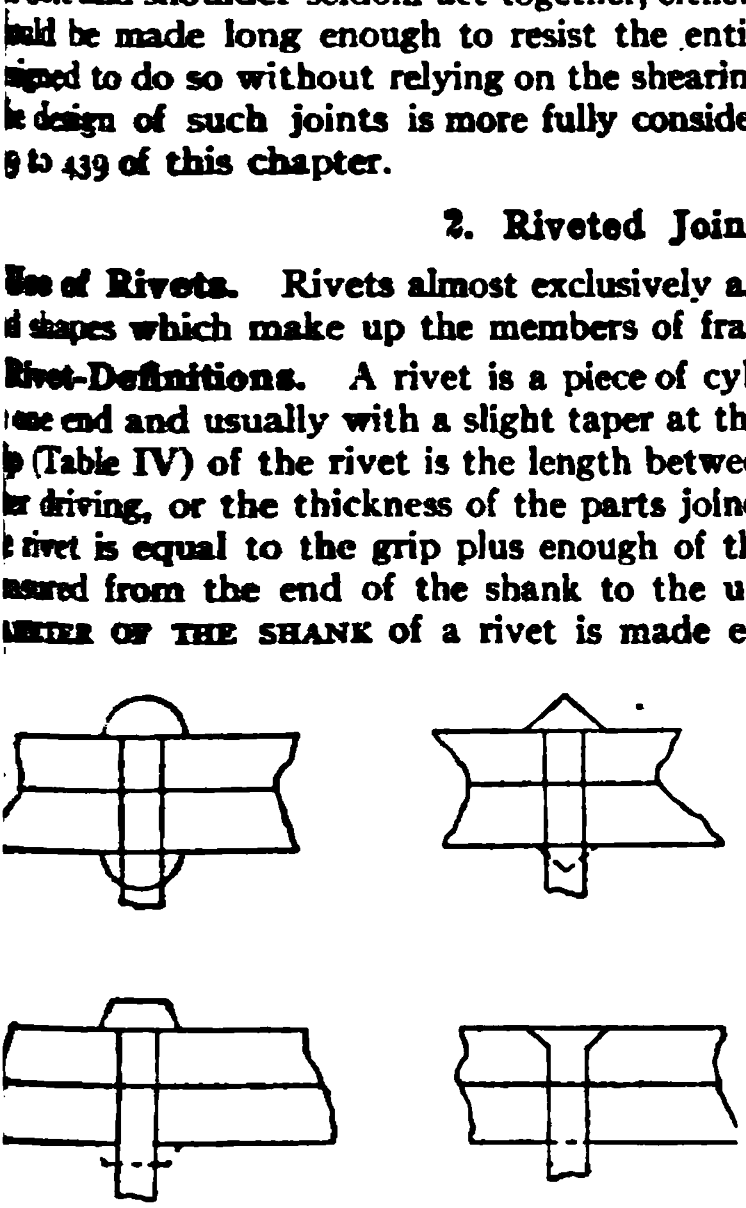

Fig. 5. Forms of Rivet-heads

Riveting consists in heating the rivet to a welding-heat, passing it through holes in the parts to be joined and forging another head out of the projecting shank. This may be done by hand-hammering; but shops use compressed-air-operated hand-hammers or large riveting-machines which form the head and cause the shank to completely fill the hole by heavy pressure on a die.

Material of Rivets. Rivets are made of soft steel and of wrought iron. Soft-steel is generally used. The head may have any of the forms shown in Fig. 5, although the first, called the BUTTON-HEAD, is the standard for structural work. The fourth or COUNTERSUNK HEAD is used where it is necessary to have a flat surface, as over a bearing-plate.

The Sizes of Rivet-Heads differ slightly at different mills. The Standa of the American Bridge Company give for the DIAMETER OF THE HEAD, one a one-half times the diameter of the shank plus ⅛ in, and for the HEIGHT of head, 0.425 times the diameter of the head. Countersunk heads have a SLO of 30° and a DEPTH equal to one-half the diameter of the shank.

The Pitch of Rivets. By this is meant the center-to-center dista between them in a line of riveting. The distance between lines of rivets, from the back of an angle or channel to a rivet-line is called the GAUGE-D TANCE. By STAGGERED PITCH is meant the arrangement of rivets midv between others on successive rivet-lines in order to decrease the section than when they are arranged in rectangular rows, and at the same time to p a greater number of rivets in a definite area. The PITCH should not be m less than three diameters of the rivet and the DISTANCE FROM THE EDGE of plate not less than one and one-half diameters, although it may be neces to make the distance less when small angles are used. The pitch of coun sunk rivets must be greater than that of button-head rivets because of greater amount of material removed.

Punching Rivet-Holes. Rivet-holes are made with power-punches. SPACING is marked on the different parts to be fastened together by mea wooden templates with holes drilled to locate the position of the rivets. W the different parts are assembled, the holes are laid out by the same TEMPL REGISTER, so that the rivets may be inserted without difficulty. PUNC makes a ragged hole. The flow of the metal under the great pressure har it and causes a loss in strength of from 11 to 33% as reported by W. C. U for soft steel. The injury may be removed by ANNEALING or by REAMING the injured part of the metal. Enlarging a ⅝-in. hole by reaming to 1 has been found to remove all the injurious effects of punching. One me practiced in the best work is to punch the holes 1/16 in less in diameter than diameter of the rivets, and to ream them to a diameter 1/16 in greater, afte parts are assembled and bolted together. This removes the greater pa the injury from punching and corrects the alinement of the holes. Table XI, page 400, and Table I, page 702.)

Drift-Pins. When the alinement of a hole is such as to prevent the inse of the rivet, it is the practice in some shops to drive in a tapered DRIFT-PI distort the holes in some of the plates sufficiently to set the rivet. This c LOCAL STRESSES and injury to the plates and should not be permitted.

Shop-Riveting is done with powerful air or hydraulic riveting-mac which may exert a pressure of from 30 to 50 tons, sufficient to upset a p head on the projecting end of the shank and to completely fill the hole though the alinement is imperfect. Contraction on cooling causes great sure between the parts, so that it is probable that in good work the rivet is little or no shearing-stress, the force being transmitted through the fric resistance of the plates.

Clearance. It is important that the designer place the rivets so they be inserted from one side and pounded on the other for HAND-WORK, or s the machine may reach them for MACHINE-RIVETED WORK. For exampl minimum distance from the inside face of the leg of one angle to a line of in the other leg must not be less than 1⅛ in for ⅞-in rivets, 1 in for ¾-in etc. In general, a distance ⅝ in greater than the diameter of the head be allowed for CLEARANCE.

Inspection. The common imperfections in riveting are LOOSE RIVET ECCENTRIC HEADS. Loose rivets may be detected by holding the hand a

e side of the rivet-head and tapping the other side with a light hammer. loose, a slight slip may be felt. The loose rivets should be marked to be cut t and replaced. The inspector should also carefully check open holes left r field-connections, and see that flattened and countersunk rivets are as called r, because such work may be done at less expense in the shop than in the ld, where it may cause delay.

The Failure of Riveted Joints may occur

(1) In TENSION, by the tearing of the plate through the line of rivets (Fig. 8).

(2) In SHEAR, by the cutting of the rivets (Fig. 7).

(3) In BEARING, by the crushing of the plate in front of the rivets, the splitting of the plate, or, in some cases, by the shearing out of the sections in front the rivets. In a careful design of a joint the strength against failure by each these methods must be investigated (Fig. 6 and Fig. 9).

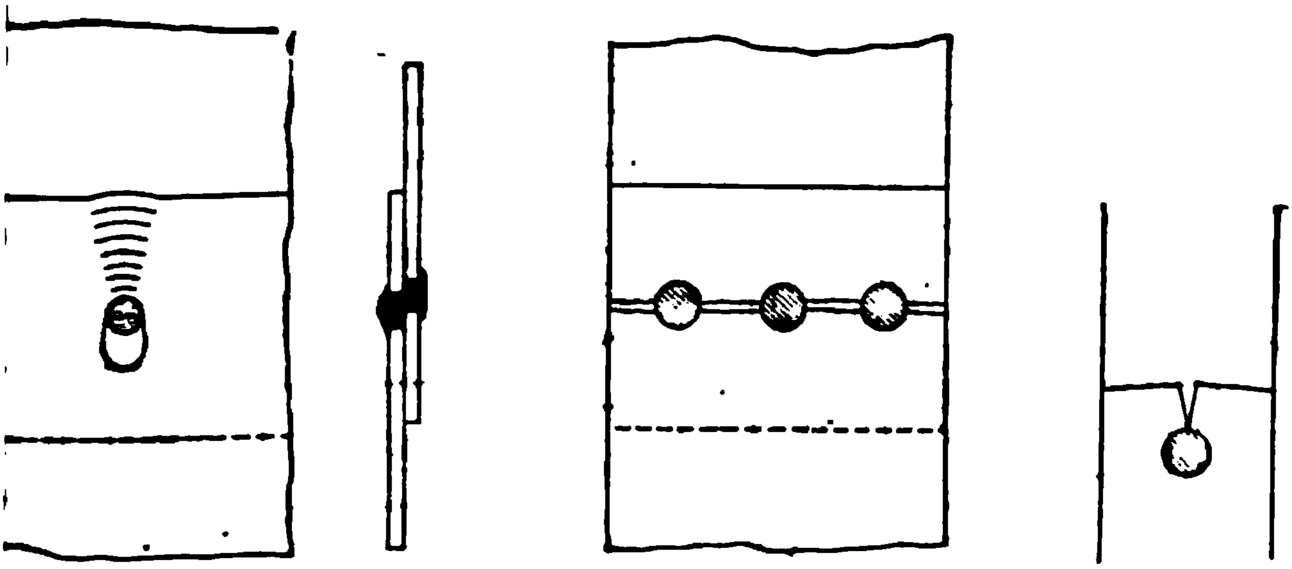

Fig. 6 Fig. 7 Fig. 8 Fig. 9

Figs. 6 to 9. Methods of Failure in Riveted Joints

The Steps in the Design of any type of riveted joint are, (1) the selection of the size of the rivet to be used, (2) the determination of its shearing bearing strength and the use of the smaller value of the two to divide into total load to be transmitted and thus determine the number of rivets, the arrangement of the rivets in the plate and the investigation of its strength tension at the dangerous section.

The Size of Rivets is determined in part by SHOP-PRACTICE. Holes cannot be punched in plates which are thicker than the diameter of the punch. following table gives the size of rivets used with plates of different thickness. e specifications for structural work require all rivets to be ¾ in, except re thick plates require larger ones.

Thickness of plates	Size of rivets
¼ to 7/16 in	⅝ in
½ to ⅝ in	¾ in
11/16 to 13/16 in	⅞ in
⅞ to 1 in	1 in

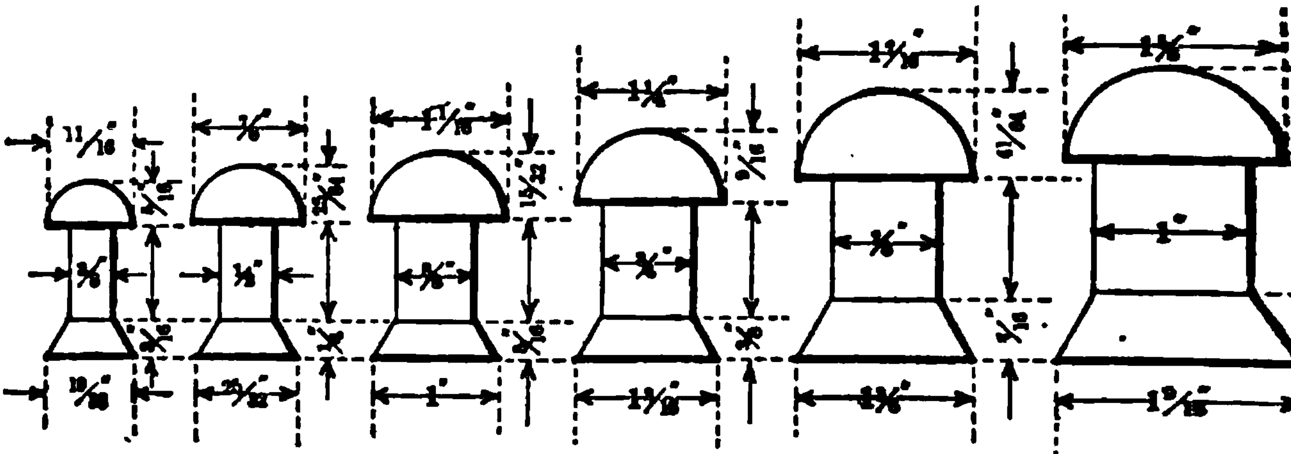
ables II and III give the SHEARING and BEARING VALUES for different sizes rivets in plates of different thickness for two values of working stresses each; r at 7 500 and 10 000 lb per sq in and bearing at 15 000 and 18 000 lb per in. Values for higher stresses can be figured by proportion from these tables. lower stresses should be used with wrought iron or in parts subjected to loads; the higher stresses where only constant or dead loads are present.

The SHEARING VALUE is equal to the area of the rivet multiplied by the work
stress; the BEARING VALUE is equal to the area of the projected surface un
pressure multiplied by the working stress in bearing, or, if

t = the thickness of the plate;
d = the diameter of the rivet;
and S_b = the working stress in bearing;
then the bearing value $P = dtS_b$

The Shearing and Bearing Values may be taken directly from the tab and if a rivet is in double shear, twice the quantity in the table is to be used its SHEARING VALUE. Quantities above the heavy broken lines are BEAR VALUES greater than the values in single shear, so that for these conditions, number of rivets necessary in a joint required to transmit a certain loa determined by dividing the load by the value in single shear. If rivets are double shear, the number of rivets required is found by dividing the load by BEARING VALUE.

Rivet-Proportions.* The following diagrams show various rivet-proporti including the dimensions of shanks and of finished and countersunk heads:



FINISHED HEADS

Diam head = 1½ diam of shank + ⅛" depth of head = 45/100 diam of head

COUNTERSUNK HEADS

Depth of head = ½ diam of shank. Bevel of head = 60°

* These proportions vary slightly at different mills and in different handbooks

Conventional Signs for Riveting. The following diagrams show some conventional signs for riveting:

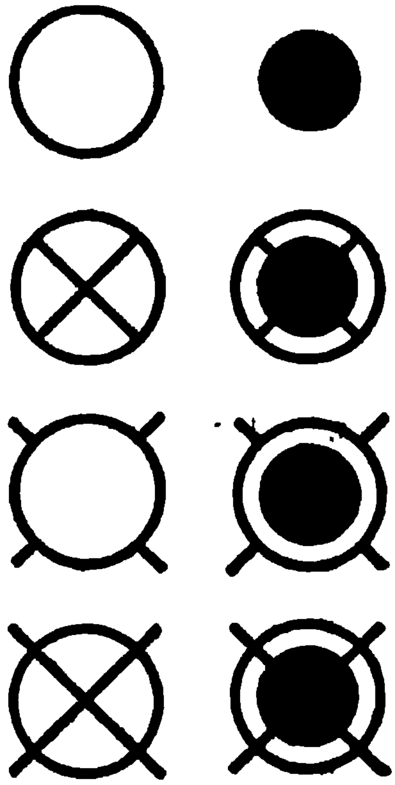
SHOP FIELD

Two Full Heads

Countersunk Inside (Farside) and Chipped

Countersunk Outside (Nearside) and Chipped

Countersunk both Sides and Chipped

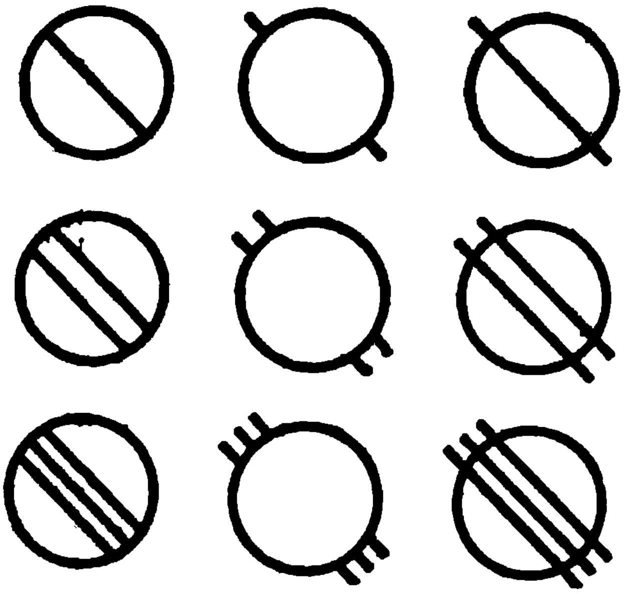


INSIDE (FARSIDE) OUTSIDE (NEARSIDE) BOTH SIDES

ttened to 1/8 in high or Countersunk and not Chipped

Flattened to 1/4 in high

Flattened 3/8 in high



s system, designed by F. C. Osborn, has for its foundation a diagonal cross present a countersink, a blackened circle for a field-rivet and a diagonal for a flattened head. The position of the cross with respect to the circle, outside, or on both sides, indicates the location of the countersink; and y, the number and position of the diagonal strokes indicate the height ition of the flattened heads. Any combination of field, countersunk ttened-head rivets liable to be used may be readily indicated by the bination of the above signs.

…e of Riveted Joints. Riveted joints are used in building-construction (1) in tie-bar splices, (2) in floor-beam connections, (3) in the joints of trusses, (4) in riveted girders, and (5) in column-connections.

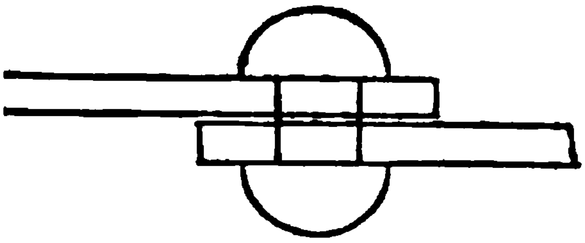

Fig. 10. Lap-joint

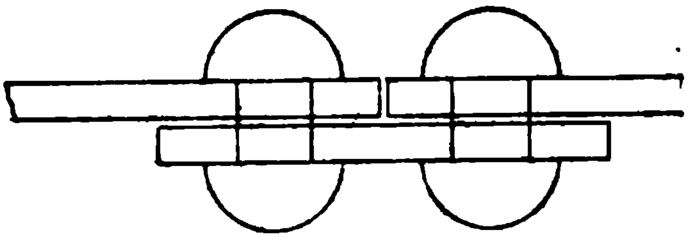

Fig. 11. Butt-joint with Single Cover-plate

…licing of Tie-Bars. Tie-bars may be spliced by a LAP-JOINT (Fig. 10); …a BUTT-JOINT with a single cover-plate (Fig. 11); or by a BUTT-JOINT …h two cover-plates (Fig. …).

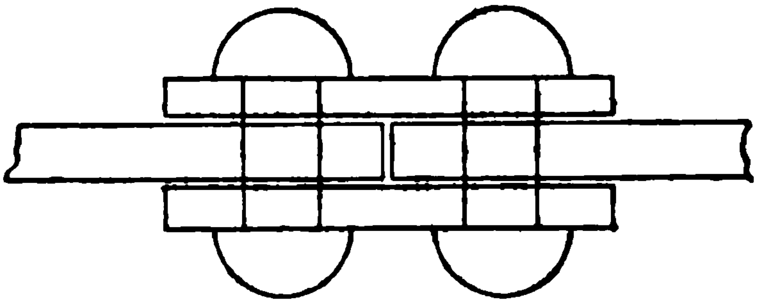

Fig. 12. Butt-joint with Two Cover-plates

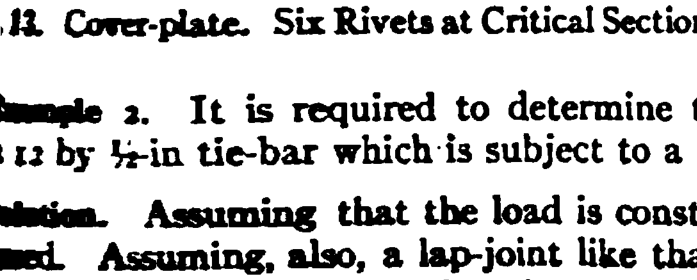
…he Butt-Joint is symmet…l and more efficient than …others because of the absence …y tendency to bend when …er a load. The net area of …cover-plates at the section …ugh the rivets at the end of …main plate must be equal to …net area of the main plate through the rivets at the end of the cover-plate. … 14 shows a better arrangement of rivets than that in Fig. 13, because less … is removed at the critical section of the cover-plates. In some cases it may be necessary to make the aggregate thickness of the cover-plates greater than the thickness of the main plates.



…13. Cover-plate. Six Rivets at Critical Section

A joint with one line of rivets is said to be SINGLE-RIVETED, one with two lines DOUBLE-RIVETED, and one with more than two lines, CHAIN-RIVETED.

…ample 2. It is required to determine the number of rivets in the splice … 12 by ½-in tie-bar which is subject to a tensile force of 65 000 lb.

…ution. Assuming that the load is constant, the stresses in Table III may …ed. Assuming, also, a lap-joint like that in Fig. 15, and ¾-in rivets, the …e in shear of one rivet is found to …4 420 lb and the bearing value …nst a ½-in plate, 6 740 lb. The …ber of rivets is determined by the …r to be equal to 65 000 divided by …0, or fifteen. Since sixteen rivets … required to complete a figure …ller but similar in arrangement to … shown in Fig. 15, this number is …. There is some latitude possible in the spacing of the rivets, but with a …h of 12 in, the horizontal gauge-lines are placed 1½ in apart for symmetry. …e pitch P, as shown in Fig. 15, is required to be three times the diameter …e rivet, this diagonal pitch across the rivet-spacing must be 2.25 in, or

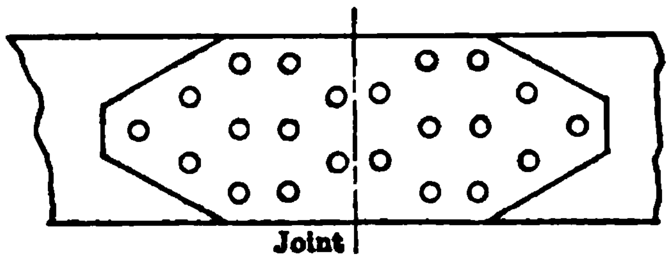


Fig. 14. Cover-plate. Four Rivets at Critical Section

greater. The length of the horizontal or third side of the right-angled trian having an hypotenuse of 2.25 in and a vertical altitude of 1.5 in, is 1.68 which requires that this dista *ED*, etc., be 1.75 in, if measu in multiples of ¼ in.

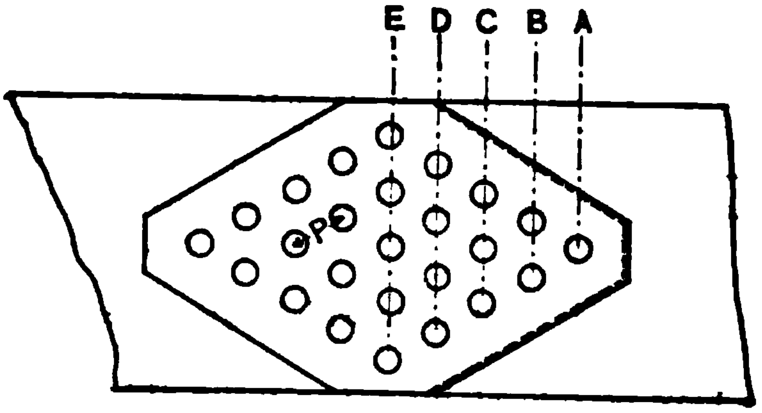

Fig. 15. Rivet-spacing in Cover-plate

Floor-Beam Connectio The two following examples lustrate common types of fl beam connections.

Example 3. It is required determine the number of ¾ rivets to connect a 10-in 25.4 I beam supporting 24 000 lb a 15-in 42.9-lb I beam, usin shearing-stress of 10 000 lb per sq in and a bearing-stress of 18 000 per sq in.

Solution. From the table of properties of standard I beams, pages 354–5, thickness of the web of the 10-in 25.4-lb beam is found to be 0.31 in, say 5⁄16 and of the 15-in 42-lb beam, 0.41 in, say 7⁄16 in. Referring to Table III, p 419, the bearing values for a ¾-in rivet for these thicknesses of webs are spectively 4 210 lb and 5 890 lb. The shearing value of the rivet is 4 420 The rivets in the 10-in beam are in double shear; hence the bearing value g erns. The number of rivets, then, is 12 000, the end-reaction, divided by 4 or 3. For the 15-in beam the shearing value is less, and the number of ri required is 12 000 divided by 4 420, or 3. Hence two standard connect angles, 6 by 4 by ⅝ in and 5 in long, may be used. Each has three holes in leg and two in the other. The leg with three holes is placed on the 10-in b with the rivets in double shear, and the leg with two holes is connected to 15-in beam; thus, in the latter case there are four rivets where only three required for strength. They are driven in the field during the erection of structure and the working stress is accordingly made less in most specificat because of the better work possible with the heavy machines used in shop-w than with the tools available in the field.

Example 4. It is required to determine the number of ¾-in rivets i 4 by 4 by ½-in angle-bracket attached to an 18-in 54.7-lb beam and supp ing a 10 by 12-in wooden beam on which there is a load of 18 000 lb.

Solution. The rivets are in single shear with a shearing-resistance of 4 42 taken from Table III. The thickness of the web of the I beam is 7⁄16 in, gi a bearing value of 5 890 lb. Dividing 9 000 lb, the end-reaction, by 4 42 the controlling value, we find that two rivets are insufficient. The bracket be fastened with three ¾-in rivets with a spacing of 4 in. Two ⅞-in ri are sufficient to hold the bracket.

Rivets in Plate Girders. The methods of determining the rivets in p and box girders are given in Chapter XX.

Bending Stress in Rivets. While the BENDING STRENGTH of PINS at joints of articulated trusses is always investigated, this is never done in case of RIVETS. A hot rivet properly driven is, when cold, under a te stress which is nearly equal to the elastic limit of the material. This c great pressure between the plates and a consequent frictional resistanc movement, which, under the usual conditions, equals the allowed shearing- on the rivet; and so, until an INITIAL SLIP occurs, there can be no BEN STRESSES in the rivet. In the case of very long rivets driven in holes w

ere is an imperfect alinement of the plates and a consequent difficulty in aking the rivets fill the holes completely, it is not probable that any large ading stresses can occur in the rivets of a structure. This has been avoided n a few structures for which long TAPER RIVETS were specified to be used in oles REAMED with TAPERED REAMERS, thus insuring a perfect filling of the holes.

Working Stresses. Tables II and III are based on stresses which approximate those used in the best practice. Table II is used for the few structures ade of WROUGHT IRON and for those places in steel structures that are subject o severe conditions of service, as in the floor-systems of bridges. Table III s used for ordinary structural work made under the conditions governing in odern shop-practice. For comparison, the following stresses taken from the pecifications of Theodore Cooper for Steel Railroad Bridges and Steel Highway ridges are given:

Specification for	Allowable stresses on rivets, lb per sq in	
	Bearing	Shear
Steel railroad bridges	15 000 (12 000 on floors) 22 500 for laterals	9 000 (7 200 on floors) 13 500 for laterals
Steel highway bridges	18 000 (14 400 on floor-beams) 27 000 for laterals	10 000 (8 000 on floor-beams) 14 000 for laterals

Rivets driven in the field are allowed two-thirds the value of shop-driven rivets.

2. Strength of Pins in Trusses*

Truss-Pins. In the design of the PINS at the joints of trusses the stresses in HEAR, BEARING FLEXURE or BENDING must be investigated.

The Shearing-Force at any section of the pin is the algebraic sum of all e forces acting on the pin on either side of the section. The stress is considered o be uniformly distributed over the cross-section of the pin. When the forces o not act in the same plane they must be resolved into vertical and horizontal mponents and the resultant of these components taken as the shear at any sired section. This may be done by the principles of GRAPHIC STATICS, or y TRIGONOMETRICAL and ALGEBRAICAL METHODS, the graphic method being, r some, the more rapid.

The Bearing Area on the pin is taken as the PROJECTION OF THE AREA OF NTACT, the area of this projection being equal to the diameter of the pin ultiplied by the thickness of the plate. The bearing is assumed to be uniformly distributed; hence for any load the intensity of the pressure may be creased by increasing the thickness of the plate or the diameter of the pin.

The Bending Moments on the pin may be found by the PRINCIPLE OF MENTS or by methods involving the principles of GRAPHIC STATICS explained Chapter IX in finding the bending moments of beams. The forces are coniered to be concentrated at the middle of the bearing-plates. If they do not e in a plane with the pin they must be resolved into their vertical and hori-

* Since the introduction of rolled-steel shapes and riveted joints, pin-joints for trusses f moderate span in buildings have fallen into disuse. The general principles of their sign, however, are given here.

zontal components and these component forces in the two planes treated sep rately. The resultants in both planes at any section may be combined and single resultant force acting on the section obtained, and also the conseque stresses due to it.

In the Method of Moments a section is taken at each force in success and the moment of the forces about a point in the section found, due consid ation being given to the di tion of turning. This is d at each force on one side of pin, if the bars are arran symmetrically, and in both vertical and horizontal pla Inspection of the results usually indicate which sec has the GREATEST RESULTANT MOMENT when the horizontal and vert components, H and V, are combined. This is done by using the form $R^2 = H^2 + V^2$ since, graphically, the resultant R is the diagonal of the recta

3⅞	85 700	114 200	128 500	6⅞	478 500	638 000	717 800

Remarks. The following is the formula for flexure, $M = SI/c$, with the reductions made to adapt it to a beam of circular section:

$$M = S\pi d^3/32 = SAd/8$$

M = the moment of forces for any section through the pin;
S = the stress per sq in in extreme fibers of pin at that section;
A = the area of the section;
d = the diameter;
π = 3.14159.

The forces are assumed to act in a plane passing through the axis of the pin.
The above table gives the values of M for different diameters of pin, and for three values of S.
If the maximum value of M is known, an inspection of the table will show what the diameter of the pin must be so that S will not exceed 15 000, 20 000, or 22 500 lb, as the requirements of the case may be.

H and V. Example 6 illustrates the method for the condition of INCLINED forces acting on the pin. In Example 5 the same method is employed to determine the size of the pin in a simple joint.

Example 5. It is required to determine the size of the pin for the joint sho in Fig. 16 in the lower chord of a steel truss. The middle bar is a vertical s pension-rod to hold the chord in place.

Solution. Beginning at the section between the outer bars, the algebr sum of the forces on either side of the section is 40 000 lb, hence this is t shear. At the section next to the suspender the sum is zero; therefore th is no shear at the middle of the pin. The bearing pressure is 40 000 lb. intensity depends on the diameter of the pin and the thickness of the bars. find the bending moment on the pin the forces are considered concentrated the middle of the bars and moments taken about sections through the forc The moment at the section through the second bar is 40 000 lb × 1 in, eq to 40 000 in-lb. If moments are taken about a point between the inner for the same result is obtained. From Table VI it is found that a 2¾-in pin 20 000 lb per sq in is sufficient. From Table V the bearing value of a 2¾ pin is found to be only 33 000 lb at a stress of 12 000 lb per sq in, which mal it necessary to increase the size of the pin to 3⅝ in. The shearing value this pin is 67 000 lb. In this case the diameter of the pin is determined the bearing-stress, but it is necessary to investigate the other stresses to sure of the correct size, especially in case of heavy bearing-plates.

Bending Moments on Pins. The finding of the BENDING MOMENT due the forces acting on a pin is usually the most difficult part of the work of det mining its proper size. In the case of a simple pin, properly packed and lyi in the plane of the forces acting on it, the GREATEST MOMENT is usually the pr uct obtained by multiplying the outer force by the central distance betw the outer bars; but when the forces act in several planes the work is m complicated. The GRAPHICAL METHOD illustrated in the solution of the t following examples has some advantages; but the METHOD OF MOMENTS appl at the end of the solution of the first example is equally rapid in practi hands and capable of greater refinement in the results.

Example 6. It is required to find the bending moment on the pin of t joint, one-half of which is shown in Fig. 17. The bars are each 1 in thi the channel of the vertical member ½ in thick and the center of the han is ¾ in from the center of the channel.

Solution. Since the joint is symmetrical it is necessary to construct but o half of the force-diagram and equilibrium-polygon which really apply the joint. From the conditions of equilibrium of forces, the vertical co ponent of the inclined force is upward, and equal to the sum of the downw forces, 34 000 lb; and its horizontal component acts with the 60 000-lb for to the amount of 17 000 lb, a sufficient amount to close the force-diagra The following construction is special, in that but one-half of the entire graphi diagram is shown. This is made possible because of the symmetry of the joi the bending moment being constant over the middle of the pin.

In the diagram (Fig. 18) AB is drawn at an angle of 45° with the horizon and commencing at c, the distances are laid off to scale between the bars, the lines 1–2, 2–3, etc., drawn parallel to the forces they represent at the joi The oblique force is resolved into its components 1–4 and 1–5.

The stress-diagram (Fig. 19) is drawn as follows: On a horizontal line forces are laid off to scale in the order they occur on the pin, 1–2, 2–3, 3–4 4–1, the closing of the diagram being a check on the correctness of the valu the forces. Beginning at 1, 1–5, 5–6 and 6–1 are laid off to scale, paralle the forces in the vertical plane. From 1 the line 1–0 is drawn at an angle 45°, for convenience in making good intersections, and equal to a conveni number, say 20 000 lb, in the same scale to which the loads are drawn. T

at O is the pole of the stress-diagram, the pole-distance being 20 000 lb. From the principles of graphics the bending moment at any point on the pin equal to the intercept between the proper ray of the equilibrium-polygon and the closing line, multiplied by the pole-distance. To complete the figures, o-3 and o-4 are drawn from O, and from c cd is drawn parallel to o-2, de parallel to o-3, ef parallel to o-4 and fk parallel to o-1. In the same way is drawn parallel to o-5, st to o-6 and tn to o-1. Then according to the above principles, the moment at any section due to the forces in the horizontal plane is proportional to the ordinate at that section drawn from the line AB the line $cdefk$ bounding the equilibrium-polygon; and the moments due to the vertical forces are proportional to the ordinates drawn to the line $rstn$, the numerical value being the length of the ordinate times 20 000, the pole-distance.

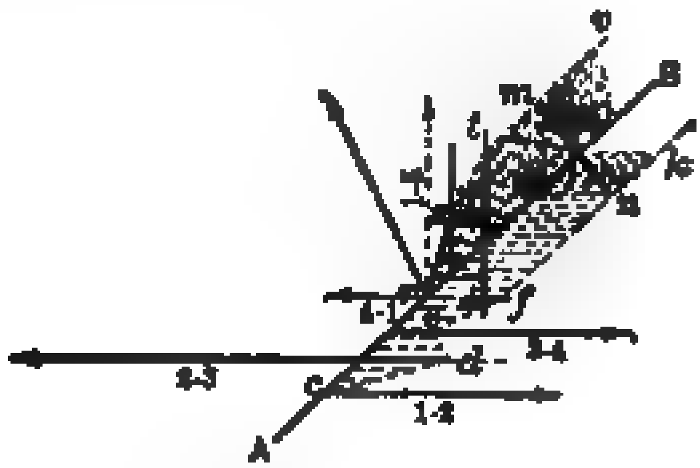

Fig. 18

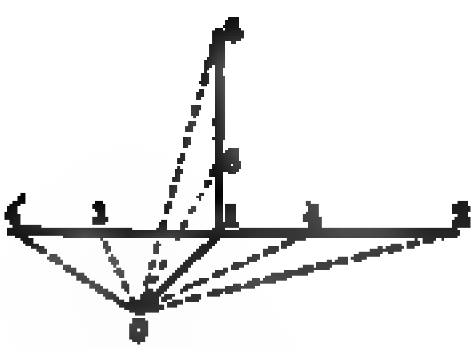

Fig. 19

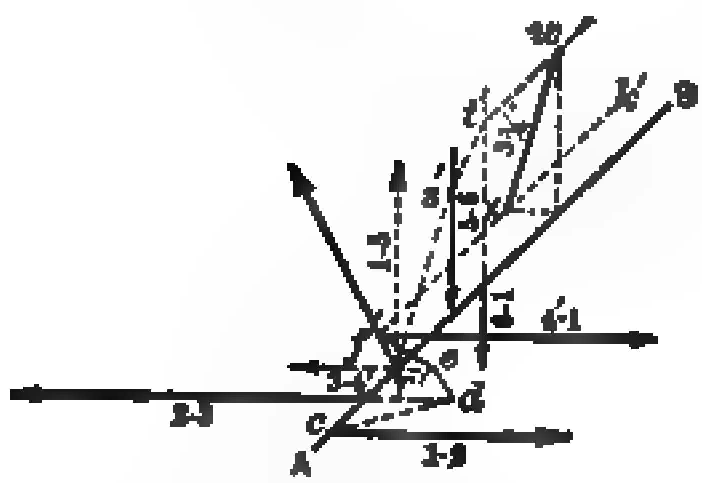

Fig. 20

Figs. 17 to 20. Pin-joint and Moment-diagrams

...re both moments are present, the resultant or true moment is proportional ...he hypotenuse of the right-angled triangle having for its sides the ordinates ...he two planes at the point in question. At X this is shown by the line mn. ...measures 2.42 in, and being the longest diagonal or hypotenuse that can ...rawn in the figure, it follows that the maximum bending moment on the ...is $2.42 \times 20\,000 = 48\,400$ in-lb.

...o find the effect of changing the arrangement of the members on the pin, ...may be assumed that the inclined bar is placed outside the inner chord-bar. ...horizontal stress-diagram then becomes 1-2, 2-3, 3-4′, 4′-1. The equilibrium-polygons become $cdef'k'$ and $r's't'w$, as shown in Fig. 20. In these polygons ...longest diagonal measures 3¾ in, which gives a bending moment of 3¾ ...20 000 lb = 75 000 in-lb, showing that the arrangement of the eye-bars in ...17 is better. As a rule the bending moment is less when those forces that

oppose each other are placed together. It may be further reduced by ma
the outside bar one-half the thickness of the main horizontal bars.

To check by the METHOD OF MOMENTS the value of the maximum ben
moment obtained by the GRAPHIC METHOD for the first arrangement, the
ments of the forces in the horizontal plane are taken about r. This gives

$$M_h = 38\,500 \text{ lb} \times 3.0 \text{ in} + 38\,500 \text{ lb} \times 1.0 \text{ in} - 60\,000 \text{ lb} \times 2.0 \text{ in}$$
$$= 34\,000 \text{ in-lb},$$

which is the value of the moment in the horizontal plane across the midd
the pin.

In the vertical plane moments are taken about a point t, giving

$$M_v = 34\,000 \text{ lb} \times 1.5 \text{ in} - 22\,000 \text{ lb} \times 0.75 \text{ in}$$
$$= 34\,500 \text{ in-lb}$$

From these component moments the resultant maximum bending moment

$$M = \sqrt{34\,000^2 + 34\,500^2} = 48\,400 \text{ in-lb}$$

Example 7. Another illustration of the GRAPHICAL METHOD of finding
bending moment on a pin is given for the joint A of the truss-diagram show

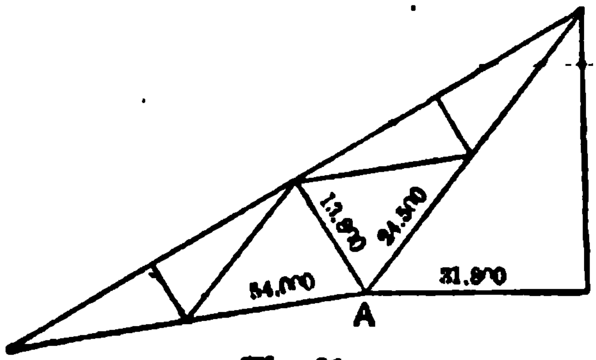

Fig. 21

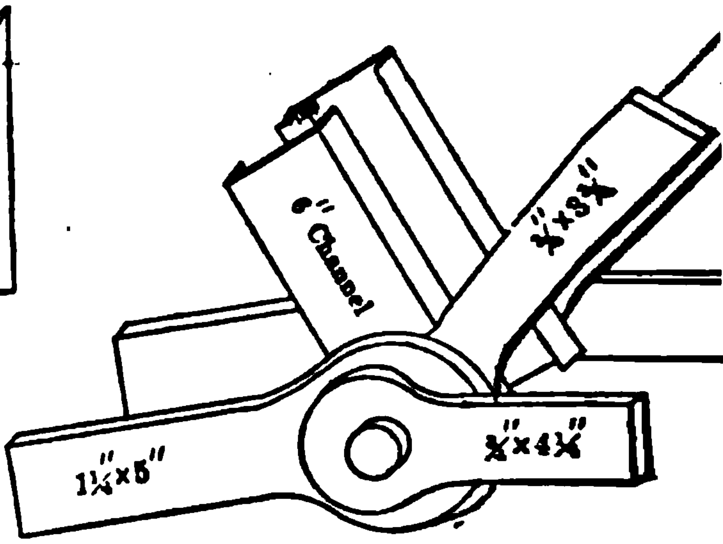

Fig. 22

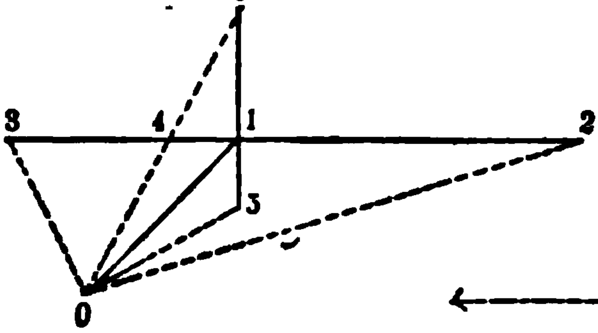

Fig. 23

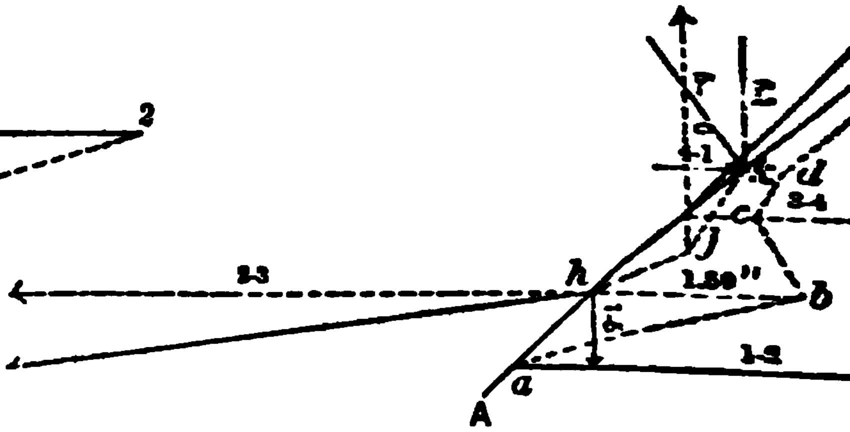

Fig. 24

Figs. 21 to 24. Force-polygons and Equilibrium-polygons for Bending Moment a Pin

Fig. 21. Fig. 22 shows the arrangement and size of the members. The s
given in Fig. 21 are for one-half the number of members at the joint.
Example 6, the symmetrical arrangement makes it unnecessary to draw

1 one-half of the force-polygon and equilibrium-polygon. The web of the nd is reinforced to make it ⅝ in thick.

lution. The line AB (Fig. 24) is drawn at an angle of 45° and ah, etc., are off to scale, equal to the distances between the members. At each point plication of a force a line is drawn parallel and to scale, to represent that e. The inclined forces are then resolved into their horizontal and vertical ponents. The force-diagram (Fig. 23) is then drawn, the horizontal forces g laid off to scale in the order in which they occur, 1–2, 2–3, 3–4 and 4–1. pole-distance is then laid off at an angle of 45° and equal to 20 000 lb to same scale of forces. The pole o is then joined with 2, 3, 4 and 1. Then Fig. 24, ab is drawn parallel to o–2, bc to o–3, cd to o–4 and de to o–1. In same way the line $hjkB$ is drawn. From inspection it is seen that hb is the est intercept, even longer than any diagonal that may be drawn from the emities of the horizontal and vertical intercepts at any point along AB. the same scale that makes o–1 represent 20 000 lb, hb represents 31 800 in-lb; efore the bending moment on the pin is 31 800 in-lb. In Table VI a pin in in diameter, at a fiber-stress of 20 000 lb per sq in, has an allowable ment of 35 500 in-lb, and in Table V a bearing value on 1 in of 31 500 lb. ure of 31 800 lb on ¾ in is equal to 42 400 for a 1-in bar; so it is necessary e a larger pin to accommodate the bearing requirement. From Table V n 3½ in in diameter is found to be necessary. The shearing value of this is 72 000 lb more than twice the load, so, again, it is the bearing that con- s the size of the pin. If the thickness of the bars is increased the diameter he pin may be reduced to 3 in.

4. Strength of Bolts in Wooden Trusses and Girders

he Working Stresses for Bolts on which Table VII and Table VIII are puted are based on a FACTOR OF SAFETY of five applied to the average of y tests on dry timber. In some specifications it is permitted to increase the ING PRESSURE between timber and bolts as much as 50% above that per- ted for short struts. The values in the tables are somewhat less than the s on large trusses made at the Massachusetts Institute of Technology, in h would indicate as safe values. These were reported in the Engineering rd, November 17, 1900. Table IX gives the allowable maximum tension, r and bending moments for wrought-iron and steel bolts.

nds of Stress in Bolts. BOLTS in wooden trusses are subject to the e kinds of stress as the RIVETS and PINS in steel structures. When the s joined are less than 2 in thick and the bolts are tightly drawn up so as evelop considerable frictional resistance between the pieces, the bolts are rtioned to resist the total force in SHEAR and in BEARING. When the s are more than 2 in thick the BENDING is taken into account and the bolts t be investigated for stresses in SHEAR, in BEARING and in BENDING. The r is assumed to be uniformly distributed over the cross-section of the bolt, the BEARING AREA is the area of the projection of the bolt on the timber, h area is equal to the diameter of the bolt multiplied by the length in con- . The BEARING STRENGTH is given as a property of the bolt although its p depends upon the crushing strength of the timber. The BENDING MO- T on the bolt is found in the same manner as for pins in steel trusses, ugh the cases are usually less complicated.

strations of the Use of Bolts. The principles involved in the use of in wooden trusses and girders and in the use of the tables may be best ated by the solution of examples in each of the following cases:

(1) Bolts in tie-beams, thin pieces.
(2) Bolts in girders to support brackets.
(3) Bolts as pins in the joints of trusses.
(4) Bolt-and-strap joints in trusses.
(5) Bolts under tension to hold the foot of a rafter.

(See, also, "Joints in Wooden Trusses," Chapter XXVIII, pages 1149 to

Case 1. Bolts in Tie-Beams, Thin Pieces. Tie-beams of wooden tr when longer than 30 ft, are usually made up of a number of pieces. This struction is cheaper than the use of a single stick. Two-inch planks b together are generally used. The location of the joints in the courses of p and the number and size of the bolts are the special considerations in the d of such a joint. In general, the joints in adjacent courses are placed a apart as possible and not more than two joints are placed opposite each in the same section. The simplest case is that of a plain FISH-PLATE JOIN a common BUTT-JOINT with two cover-plates as shown in Fig. 12. The nu of BOLTS for such a joint is found in the same way as the number of RIVE steel tie-bars. The bolts must be spaced as required in the second column each timber in Table VII, to provide against shearing in front of the bolt.

joints in *A* and *A′* this must be transmitted to *B* and *C* in order to pa
point *X*.

Assuming that 29 000 lb, one-half the tension, is carried on plank *A*
transmitted to *C* by the shear and bearing on the bolts, and dividing t
7 850 lb, the allowable shear on a 1-in bolt, four bolts are found to be nece
But the bearing value of a 1-in bolt in Douglas fir 2 in thick, is only 2 4
which makes twelve bolts necessary. These are required in the distanc
12 ft.

From the distances in Table VII, it is found that the end-bolts must be
from the ends of the planks, say 6 in; this leaves 11 ft, in which distanc
bolts are to be arranged. If four bolts are placed in pairs, two at each e

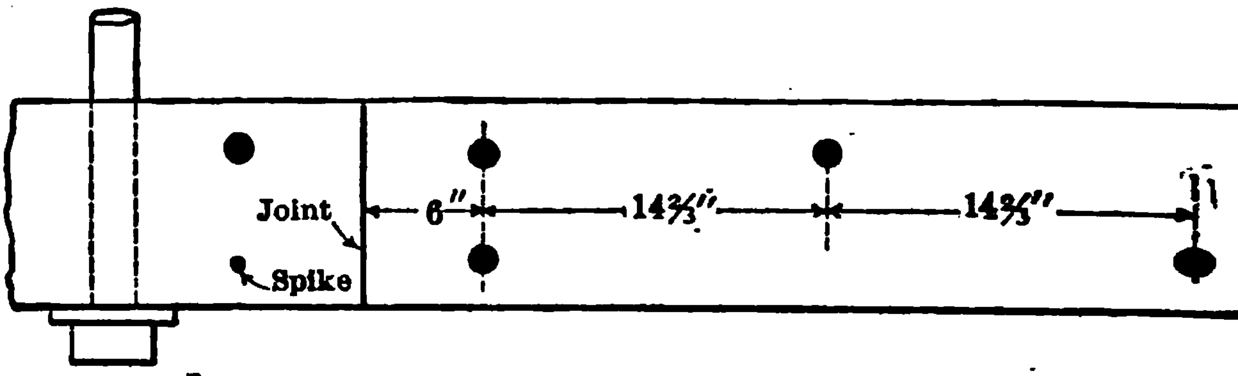

Fig. 26. Elevation of Beam Opposite *X* of Fig. 25

shown in Fig. 26, the intermediate spaces are 14⅔ in. The bolts bind the
together better if they are staggered, as indicated in Fig. 26, and not pla
the middle line.

The number of bolts mentioned is sufficient to make the splice, but
should be bolts in the distance *YY′*, and between the ends and *X* and
bind the planks together. These need not be as large or as close toget
the others; ¾-in bolts spaced 2 ft are sufficient. There should be tw
at the end of the beam. Each bolt should be driven through a hole of th
size as the bolt and the nuts should be screwed up tight.

Case II. Bolts in Girders to Support Brackets. The construction
in Figs. 27 and 28 is commonly used in cases in which the requirements
allow the girder to project its full depth below the joists. The BOLTS sh
Fig. 27 must be investigated for BEARING and SHEAR, and those shown in F
for BEARING, SHEAR and BENDING. In either case the SHEARING VALUE of t
in single shear must equal or be greater than the greater of the forces *S* o

The BEARING per inch on the wood of the girder, when *B* is in inches, i

$$(S + S')/B$$

This must be kept within the values given in Table VII for the timber used. For the case shown in Fig. 28 the BENDING MOMENT in pound-inches is

$$M = SL/2 \quad \text{or} \quad M = S'L/2$$

whichever is the larger. B and L are measured in inches and S in pounds.

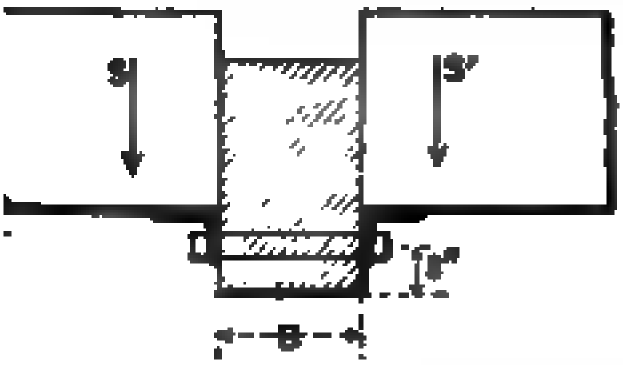

Fig. 27 Fig. 28

Figs. 27 and 28. Bolts Supporting Brackets on Girders

Example 9. For the construction shown in Fig. 27 it is required to determine the number and size of bolts, the Douglas fir girder being 8 by 14 in, with a span of 14 ft, and the Douglas fir joists 3 by 12 in, with a span of 20 ft, center to center of girders. The floor-load, including the floor, is 60 lb per sq ft. The strips are 4 by 3½ by ¾ in.

Solution. The floor-area supported by the girder is 14 by 20 ft. At 60 lb per sq ft, the load is 14 × 20 × 60 = 16 800 lb. The load S, on one side, is 8 400 lb.

A ¾-in bolt has a shearing-value of 4 420 lb. Hence two bolts are necessary to satisfy the shearing condition. The bearing value of the bolt in the wood, across the grain, is, from Table VIII, 187 lb per inch of length, or 1 496 lb for the width of the girder. The number of bolts required, then, is 16 800 divided by 1 496 or approximately 11, which gives a spacing of about 15 in.

Example 10. In the construction shown in Fig. 28, the girder is 6 by 14 in, of Douglas fir and has a span of 12 ft. The joists are 2 by 12 in and have an 18-ft span, center to center of girders. The floor-load is 65 lb per sq ft. There are 3 by 4-in strips on the sides of the girder. The distance L is 3 in. It is required to find the number and size of bolts to be used.

Solution. The total load on the girder is

$$12 \times 18 \times 65 = 14\,040 \text{ lb}$$

$$S = 7\,020 \text{ lb}$$

The bearing load per inch of thickness of the girder is

$$\frac{14\,040}{6} = 2\,340 \text{ lb}$$

The bending moment on one side of the girder is

$$\frac{7\,020 \times 3}{2} = 10\,530 \text{ in-lb}$$

as the force S acts at the center of pressure on the bracket-strip, 1½ in from the edge of the girder.

The shear is 7 020 lb, which requires two ¾-in steel bolts at 4 420 lb for one bolt in Table IX.

The bearing (Table VIII) on a ¾-in bolt is 187 lb per inch of length; therefore it requires thirteen bolts for bearing.

The allowable bending moment on a ¾-in steel bolt is 830 in-lb, from Table
To take care of the 10 530 in-lb requires thirteen bolts. A ⅞-in steel bolt
an allowable bending moment of 1 310 lb-in, making eight of them suffici
The 3 by 4-in pieces may be held in place by thirteen ¾-in bolts spaced 1
on centers, if two of them are placed 6 in from the ends.

Case III. Bolts as Pins in the Joints of Trusses. For TIES STRUTS joined by BOLTS in manner indicated in Figs. 30 and 31 and having thickness B exceeding . the diameter of the bol the number of bolts mus computed for SHEARING, BE ING and FLEXURE.

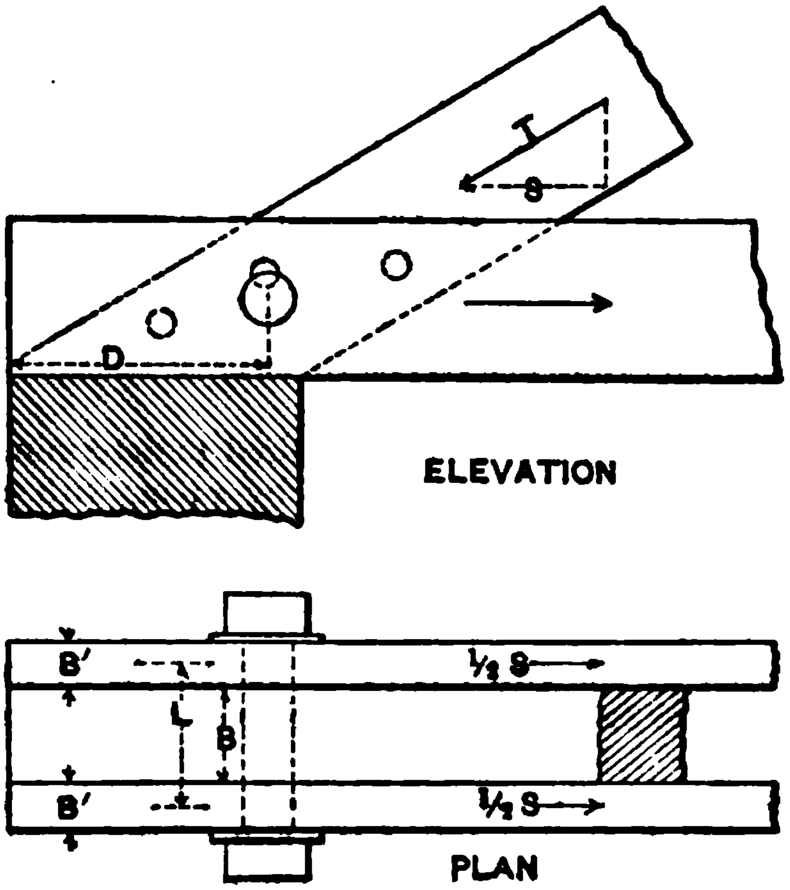

Fig. 29. Bolt through Rafter and Tie-beam

For any of these joints forces are as follows:

The single shear = $S/$

On the sections betwee and B' (Fig. 30)

The bearing on the pi inch of length = S/B or

The greater is to be used.

The bending moment = S

on the assumption of a CON UOUS BEAM, uniformly lo

If there are more bolts one, the quantities obt by the above formulas are to be divided by the number of bolts to find the to be taken care of by one bolt.

In Fig. 29, S is the horizontal component of the thrust T.

Example 11. It is required to determine the diameter of a bolt for a like that shown in Fig. 29. The rafter is 6 by 10 in, of Douglas fir, the tie-beams 3 by 10 in, of the same material, the thrust in the rafter 30 000 lb, and its inclination 30°.

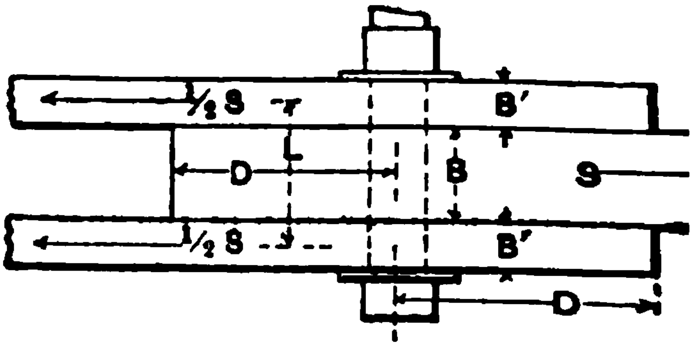

Fig. 30. Bolt in Wooden Tie-beam

Solution. The horizontal component of 30 000 lb at 30° is practically 26 000 lb. Then S = 26 000 lb and the shear = 13 000 lb. B = 6 in and L = 9 in.

Bearing per inch of length on the bolt = 26 000/6 = 4 333 lb
Bending moment = 26 000 × 9/12 = 19 500 in-lb

In Table IX, a 1⅝-in steel bolt is found to be necessary to resist a sh 13 000 lb, and a 2¼-in bolt for a bending moment of 19 500 in-lb. To 4 333 lb end-bearing pressure on 1 in a larger bolt is required than is gi Table VII. Dividing 4 333 by 1 200, the allowable bearing on Dougla 3⅝-in bolt is found to be necessary. This is larger than it is desirable so the joint must be redesigned with a view to reduce the bearing press

bolt. If an 8 by 8-in strut and 4 by 8-in tie-beams are used, B becomes 8 and L 12 in. This gives

Bearing pressure = 26 000/8 = 3 250 lb per inch of length of the bolt
Bending moment = 26 000 × 12/12 = 26 000 in-lb

e total shear at the section on one side of the strut is the same as before. From Table VII it is found that a 2¾-in bolt is large enough to provide for e bearing and that a 2½-in bolt is sufficient for the bending as given in Table . Hence if an 8 by 8-in strut is used, there must be a 2¾-in bolt and e distance D must be 15½ in (Table I).

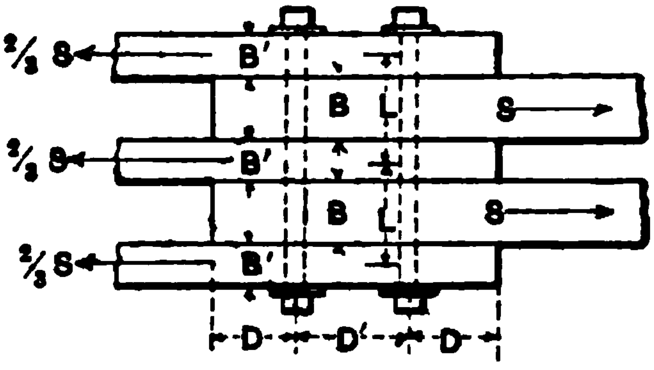

Fig. 31. Bolts in Wooden Tie-beam

Example 12. For the same construction as in Fig. 29 and the same conditions as in the first part of Example , it is required to determine the size the bolts when it is necessary to e three.

Solution. The shear, bearing, and nding moment are the same as in ample 11, but because there are ee bolts each quantity is divided by 3 to determine the force resisted by ch.

Shear = 13 000/3 = 4 333 lb and requires a ¾-in steel bolt (Table IX)
Bearing = 4 333/3 = 1 444 lb and requires a 1¼-in bolt (Table VII)
Bending moment = 19 500/3 = 6 500 in-lb, and requires a 1½-in steel bolt able IX).

In this case the bending moment determines the size of the bolts, which may arranged as shown by the dotted circles in Fig. 29.

Example 13. It is required to determine the diameter of the bolt for the struction shown in Fig. 30, in which the inner beam is of Douglas fir and y 8 in in section, and the outer beams 3 by 8 in, the tension being 24 000 lb.

Solution. $S = 24\,000$; $B = 6$ in; $L = 9$ in.

Single shear on the bolt = 24 000/2 = 12 000 lb
Bearing-pressure per inch of length of bolt = 24 000/6 = 4 000 lb
Bending moment = 24 000 × 9/12 = 18 000 in-lb

From Table IX a 1¼-in steel bolt is found sufficient to resist the shear, and ¼-in bolt large enough to resist the bending. In Table VII the largest bolt sidered, 3 in, is too small in bearing value. Dividing the load to be resisted 1 200 gives 3⅓ in, as the diameter necessary to resist the bearing. The ance D must be 4 000/(2 × 130) + 3⅓ in or 18¾ in.

Example 14. If two bolts are used, one behind the other, it is required to rmine the diameter of the bolt that should be used, the conditions and ing being the same as in Example 13.

Solution. Dividing the quantities obtained in Example 13 by 2,

Single shear = 6 000 lb and requires a ⅞-in steel bolt
Bearing = 2 000 lb and requires a 2-in bolt
Bending moment = 9 000 in-lb and requires a 1¾-in steel bolt

e allowable bearing on a 1¾-in bolt is (2½ %) less than the required amount, ut in general, since the other requirements are more than satisfied, the r bolt would be used. For the 1¾-in bolt, the distance D is 9¼ in. The e between the bolts may be increased somewhat beyond the value given in

Table VII, and they may be located out of the same line as a further pr tion against splitting.

Case IV. Bolt-and-Strap Joints in Trusses. The construction sho Fig. 32 is sometimes used to connect the foot of the rafter of a wooden to the tie-beam. When the distance D is sufficient to resist the shear d the thrust of the rafter, the strap is of value only in holding the rafter in and there are no greater pressures brought upon the BOLT. When it is i sible to make D the necessary length, the BOLT and STRAP must be des to resist the full force in the direction of the STRAP.

As the STRAP is usually not more than from ½ to ¾ in thick, its w is such that the bearing between it and the rafter is small comp with that between the BOLT rafter. The forces acting on the are the only ones that need sideration. These are:

SINGLE SHEAR = $S/2$ = the sion in the strap on one side

BEARING PRESSURE per inc length = S/B, where B is the w of the tie-beam in inches

BEARING PRESSURE per inc length between strap and bolt =

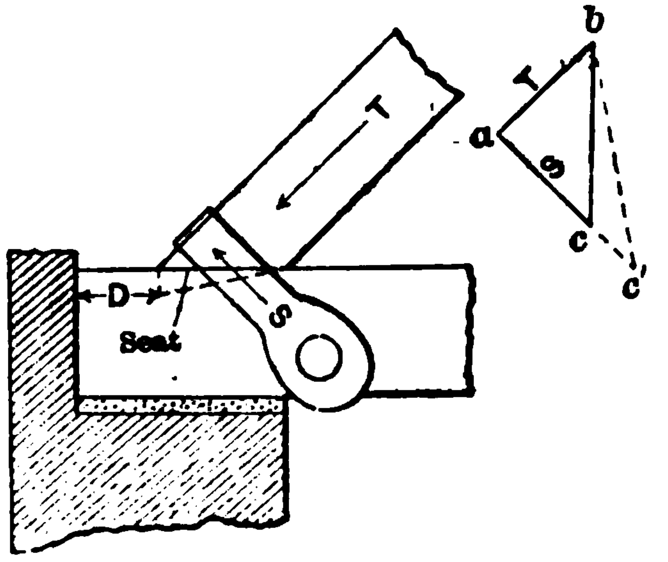

Fig. 32. Strap and Bolt at Foot of Rafter

To find the value of S, the f polygon is drawn as shown at the in Fig. 32. T is drawn parallel t rafter and with a length, to a venient scale, equal to the thrust. From the end a an indefinite line is d parallel to the axis of the strap, and from b another line perpendicular to SEAT of the rafter. These intersect at c, so that ac, measured by the scale used in laying off T, is the magnitude of the force S in the strap. If rafter rests on top of the beam, bc is vertical, but if the tie-beam is dappe shown by the dotted line, the line from b is drawn perpendicular to the bo of the notch, making the intersection at c'. It is seen that notching the beam in this way increases the stress in the strap.

Example 15. It is required to determine the size of a strap and pin to hold the rafter without notching into the tie-beam of a long-leaf yellow- king-post truss. The rafter is 6 by 6 in, is inclined at an angle of 45° a under a compressive stress of 18 000 lb. The tie-beam is 6 by 8 in in sectio

Solution. Since the inclination is 45°, a consideration of the force-pol in Fig. 32 shows ab equal to ac, so that

The force S = the thrust T = 18 000 lb
Single shear on bolt = 18 000/2 = 9 000 lb
Tension in strap on one side = 9 000 lb
Bearing pressure per inch of bolt against wood = 18 000/6 = 3 000
Bearing pressure in pounds per inch between strap and bolt = 9 00
in which t equals the thickness of the strap.

The allowable pressure between the strap and the top of the rafter is 3 per sq in (Table VII), which, on the 6-in rafter, gives

Allowable load per inch of width of strap = 6 × 350 = 2 100 lb

The strap then must be 18 000/2 100 or 8.6 in wide. At 10 000 per in tension the necessary section of the strap is 0.9 sq in, requiring a thickn

at 0.1 in, a sufficient thickness if the strap were strong enough to develop a form pressure over the rafter. It is not good practice, however, to use such material, because of the danger of loss of strength due to corrosion. No al less than ⅜ in thick should be used in such places.

The bearing-pressure per inch, between the strap and the bolt, for a ⅜-in p = 9 000/⅜ = 24 000 lb

The bolt, then, must take a single shear of 9 000 lb, a bearing pressure of lb against the wood for each inch of length, and a bearing of 24 000 lb inch of length against the strap. From Table IX a 1⅛-in steel bolt is cient to resist the shear, from Table V a 2-in bolt is large enough to resist bearing from the strap, and from Table VII a 2¼-in bolt is found necessary esist the 3 000-lb bearing from the wood per inch of length of bolt. This es the 2¼-in bolt satisfactory for the joint.

The pressure from the bolt to the wood, however, is not parallel with the n but inclined at 45°. The allowable pressure against wood across the n is about one-fourth of that with the grain. According to the formula n in Chapter XXVIII, page 1138, the allowable pressure per square inch for case is 612 lb instead of the 1 400 per sq in allowed for direct compression h the grain. The reduced allowable pressure makes it necessary to use a n bolt, say a 5-in bolt, which would be impracticable, for it would almost cut tie-beam in two. It thus appears that this form of joint is not good design a truss of this span. For shorter s the joint may be made in rdance with the requirements n. It has the advantage of not ating any projections below the beam.

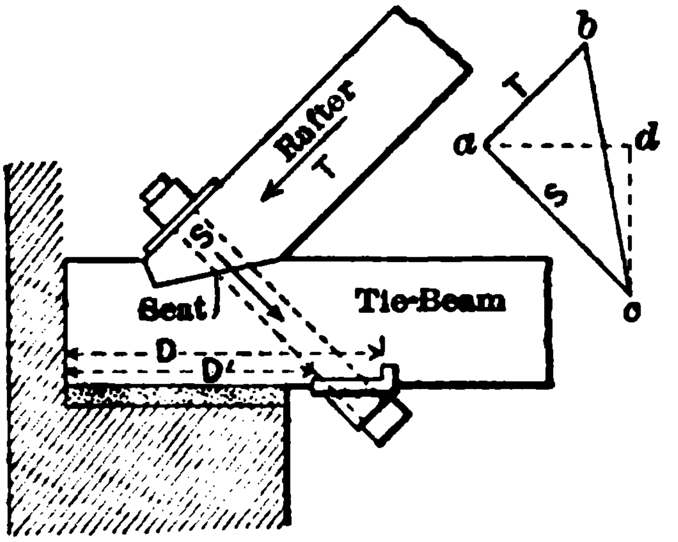

Fig. 33. Bolt in Tension at Foot of Rafter

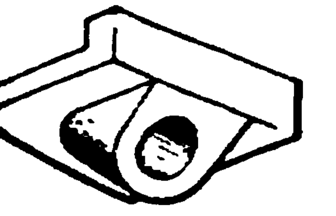
Case V. Bolts in Tension to ld the Foot of a Rafter. In the t shown in Fig. 33 the bolt is ject to DIRECT TENSION only. e amount of the tension S is found the construction explained in e IV. The rafter may be let into tie-beam or rest on top of it, the ion in the bolt being less in latter case; but it is easier to erect the truss if the rafter is NOTCHED INTO BEAM from 1¼ to 1½ in for ordinary spans and loads, to hold it while the pieces are fitted. After this is done, the holes may be bored exactly where required.



. 34. Special Washer

Whenever S exceeds about 10 000 lb for trusses made of timber for which the highest bearing stresses are allowed, a CAST PLATE, as shown in Fig. 34 and made to fit the inclination of the bolt, should be let into the tie-beam at the head of the bolt to distribute the pressure. The diameter of the hole for the bolt ld be ⅛ in larger than the diameter of the bolt. The distance D must be e sufficient to provide for the horizontal component of S, at the allowed ing stress of the material for shear with the grain.

The horizontal component is found by drawing a vertical line from c and a ontal line from a and measuring ad to the scale of the diagram. For y, this force must be less than the product of the distance D, the width of beam and the allowed shearing-stress given in Table I, page 412.

Example 16. For the same conditions as in Example 15, for the size of members and the thrust in the rafter, it is required to determine the dia of the bolt and the distance *D* for a joint of the type shown in Fig. 33.

Solution. To find *S*, draw *T* equal to 18 000 lb, at a convenient scale, parallel to the rafter. At *a*, draw an indefinite line perpendicular to the r and at *b* a line perpendicular to THE SEAT of the rafter. This makes *S* gr than in Example 15, as *ac* now scales 27 000 lb. From Table IX, a 1¾-in bolt is sufficient to take this in direct tension. The horizontal compo found as directed above, scales 19 000 lb. The width of the tie-beam is which at the allowed shearing-stress, 150 lb per sq in, gives 900 lb as the that must be cared for by each inch of *D*. 19 000 lb divided by 900 gives the required distance *D*. (See, also, Chapter XXVIII, Joints in W Trusses.)

The compression against the grain on the end of the cast-iron washer also be investigated. 19 000 lb divided by the width, 6 in, gives 3 166 lb must be resisted per inch of width of beam. At 1 400 lb per sq in, as an able working stress, this makes it necessary to set the casting 2¼ in int lower side of the beam, which exceeds the depth usual in ordinary pra Some tests made at the Massachusetts Institute of Technology on large tr and reported in 1897, indicated that for a TEST CARRIED TO RUPTURE the st prescribed for usual designs might safely be more than doubled. Tes timber under LONG-CONTINUED LOADING indicate that rupture finally for stresses approximating one-half of those developed in TESTS CARRIE IMMEDIATE FAILURE. This, and the fact that decay may affect the streng the members, emphasizes the wisdom of using CONSERVATIVE WORKING-STR in this material.

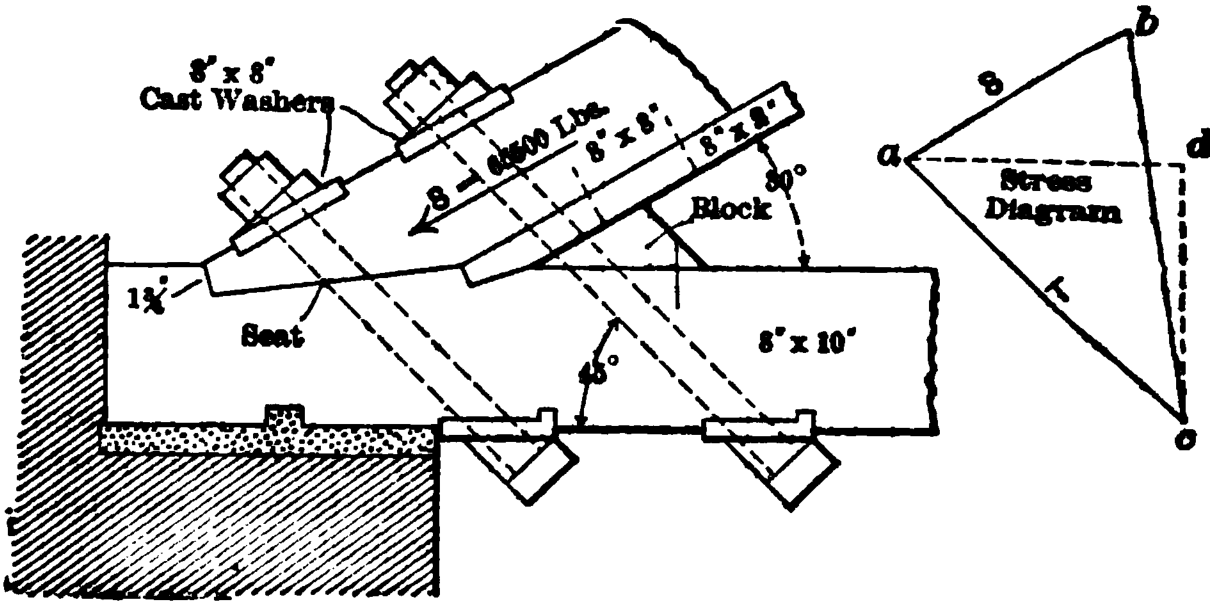


Fig. 35. Joint with Two Bolts in Direct Tension

Example 17. It is required to determine the size of bolts for the joint s in Fig. 35, the thrust being 65 500 lb and the truss-members being ma long-leaf yellow pine.

Solution. The tension in the bolts is found first by drawing the force-po as shown at the right in the figure. To the same scale that *ab* represents 6 *ac* represents 96 500 lb. If the load is equally divided between the bolts, has a tension of 48 250 lb. From Table IX this force requires a 2¼-in bolt.

The horizontal component *ad* is 68 350 lb, which must be resisted by the ing strength of the wood between the end of the cast-iron washer on the

of the tie-beam and the end of the beam resting on the wall. At 150 lb sq in, this requires 68 350/150, or 455 sq in. If the beam is 8 in wide, this ires a length of 57 in along the beam from the washer to the end.

he bearing of the cast-iron washer against the end-fibers of the tie-beam is 68 250 lb. At an allowable pressure of 1 400 lb per sq in the depth of washer should be 68 350/(8 × 1 400) = 6.1 in. This would almost cut the m in two. The ultimate strength of the wood in compression is about five s the working stress, and since a considerable part of the horizontal force be resisted by the body of the bolt as well as by the friction of the washer, probable that with washers ¾ in thick there would be little sign of weak- at the joint even when the truss is fully loaded.

heoretically the washers on the top surface of the rafter should be deter- ed by the allowable working stress in compression across the fibers. This ong-leaf pine is taken at 350 lb per sq in (Table VI, page 454). The area, , is 48 250/350, or 138 sq in. This requires a washer 11¾ in square. e 8 by 8-in washer used, assumes a pressure of 755 lb per sq in, but as the tests he Forest Service of the United States Department of Agriculture give 3 480 per sq in as the elastic limit for long-leaf yellow pine, it is very likely that re would be no signs of injury at this point, other than a SLIGHT INDENTA- , when the truss is fully loaded.

CHAPTER XIII

BEARING-PLATES AND BASES FOR COLUMNS, BEA AND GIRDERS. BRACKETS ON CAST-IRON COLUMNS*

By
HERMAN CLAUDE BERRY
PROFESSOR OF MATERIALS OF CONSTRUCTION, UNIVERSITY OF PENNSYLVA

1. Bearing-Plates and Bases

The Purpose of Bearing-Plates or Bases. When a heavily loaded umn, beam or girder is supported on a masonry wall or pier, a BEARING-PLAT BASE of suitable dimensions must be used to distribute the load so that pressure will not exceed the safe BEARING STRENGTH of the masonry (Tabl

	16×22	39 500	57 000	73 200

* These values are slightly different from those of the New York Code (1916)

Ribbed Bases. If the calculated size of a bearing-plate is so large th projection beyond the edge of the column would be more than about 6 RIBBED BASE similar to that shown (Fig. 3) for a cylindrical column is For such bases it is unnecessary to consider the transverse stresses. these bases are bolted to the columns they add greatly to the general sta of the supporting members because of the greater width of such bases.

Proportions of Ribbed Bases. The HEIGHT H of this type of base sl be approximately equal to the PROJECTION P, and the DIAMETER D equ the diameter of the column. The projection C should be at least 3 in to p the bolting of the column to the base. The THICKNESS of all parts of the c should be the same and approximately equal to the thickness of the co shell. There must be no thin webs as they result in breakage from shrin stresses.

Base-Plates for Steel Columns are usually made of STEEL PLATES and s as shown on the channel-columns in Chapter XIV, Figs. 17, 18 and 19. iron bases are sometimes used for very heavy columns. If conditio favorable to the action of corrosion the cast iron is to be preferred.

The Area of Bearing-Plates under Beams and Girders is found in the ne manner as the area of plates under columns. If the load on the beam is iformly distributed over the beam or concentrated at its middle, the required a of the plate is one-half the total load on the beam divided by the allowable aring per unit of area on the masonry; but if the load is a moving load, the eatest possible end-reaction must be divided by the allowable bearing. For ample, a heavily loaded truck standing near the end of the beam causes a essure on the bearing-plate much greater than one-half its weight. The e reaction for the actual conditions must be found by the methods explained Chapter IX.

The Thickness of the Bearing-Plate is found by the formula used to ermine the flexure of beams. It must be determined in each case. For a pical case the forces acting are shown in Fig. 5, which represents a transverse

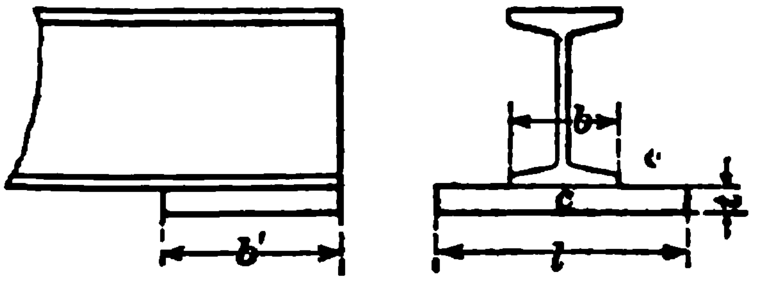

Fig. 4. Simple Bearing-plate under I Beam

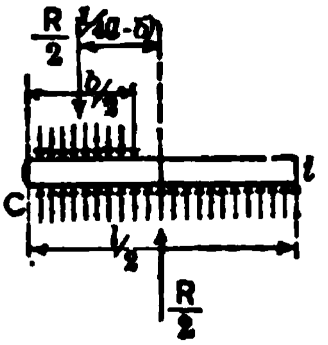

Fig. 5. Forces Acting on Half of Bearing-plate

tical section through one-half the plate. The vertical section at C, and ough and parallel with the web of the I beam, is taken through the center of plate, which is the dangerous section, or section of maximum bending mo nt.

In Figs. 4 and 5, b' is the bearing depth on the wall;
l is the length of the plate, parallel with the wall;
b is the width of the flange of the beam;
R is the load on the bearing-plate.

eplacing the uniform loads by the equivalent forces at the center of gravity each, these forces are represented by the longer arrows. The bending mo t at the section at c is the same as the moment of the concentrated forces, ing

$$M = (R/2 \times l/4) - (R/2 \times b/4)$$
$$M = R/2 \times (l - b)/4$$

s is equal to the resisting moment at the same section c, or, at stress S, c, in which I/c is the section-factor. (See Chapter XV.) This reduces to $^2/6$. Equating the bending moment and the resisting moment there results

$$St^2b'/6 = R(l - b)/8$$

$$t = 0.866\sqrt{R(l - b)/Sb'}$$

r $S = 3\,000$ for cast iron, this reduces to

$$t = 0.0158\sqrt{R(l - b)/b'} \qquad (1)$$

r $S = 16\,000$ for steel plates, it becomes

$$t = 0.00685\sqrt{R(l - b)/b'} \qquad (2)$$

Example 2. It is required to determine the length and thickness of a cas iron bearing-plate under a wooden beam which is 10 in wide and supports load of 24 000 lb. The plate is 8 in wide and bears that width on a brick w laid up in lime mortar.

Solution. The load on the plate is $24\,000/2 = 12\,000$ lb. From Table I the area of the plate is $12\,000/112 = 108$ sq in. Hence, if the width of t plate is 8 in, its length must be $13\frac{1}{2}$ in. Then, from Formula (1)

$$t = 0.0158\sqrt{12\,000\,(13\tfrac{1}{2} - 10)/8} = 1.15 \text{ in}$$

A plate $1\frac{1}{4}$ in thick would be used.

Example 3. It is required to determine the length and thickness of a st bearing-plate under the end of a 24-in 79.9-lb I beam supported on a 12-in br wall laid up in lime-and-cement mortar and carrying a load of 60 000 lb. T width of the flange of the beam is 7 in. (See Table I.)

Solution. The load on the plate is $60\,000/2 = 30\,000$ lb
The area of the plate $= 30\,000/160 = 187\frac{1}{2}$ sq in
The length of the plate is $187.5/12 = 15.6$ in

Then, from Formula (2)

$$t = 0.00685\sqrt{30\,000\,(15.5 - 7)/12} = 1 \text{ in}$$

Standard Sizes of Steel, Wall Bearing-Plates. These are given in Ta II, and are based upon ALLOWABLE PRESSURES of 112, 162 and 208 lb per sq These UNIT PRESSURES are based upon the ALLOWABLE PRESSURES of the N York and Philadelphia building laws which are pressed in tons per square foot. Because of complicated formula on which the thickness depe it is best to compute the thickness for each case.

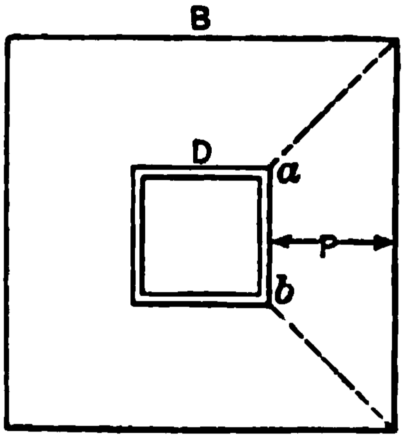

Fig. 6. Flat Bearing-plate for Column

Bearing-Plates under Columns. The gen rules already given for the proportions of RIB BASES similar to that shown in Fig. 3 are a suffic guide for detailing such bases; but in case sin FLAT PLATES are used under columns, their thick must be computed according to the principles gov ing bending. The stress in a FLAT PLATE suppo at the middle and subjected to a uniform load ca be determined by the ordinary methods of mecha The approximate solution here given is gene used in the design of BASE-PLATES and COLUMN-FOOTINGS. It gives va found to be safe in practice.

In Fig. 6, let B = the length of the side of the plate as determined by allowable pressure on the supporting masonry;
D = the side or diameter of the column;
$P = (B - D)/2$ = the projection of the plate;
t = the thickness of the plate;
A' = the area of the plate outside the column;
w = the allowable bearing pressure on the masonry due to load on the column.

Then in Fig. 6, the pressure on one-fourth of A', shown enclosed by the d lines in the figure, causes shearing and bending stresses in the section o plate along the line ab. Considering the part enclosed and taking mo about the section ab, the following equation is obtained from the usual

-moment formula. (See Chapter XV, page 557.) That is, the resisting ment equals the bending moment, or

$$SI/c = \tfrac{1}{4}A'Pw$$

r the rectangular section at ab, this may be written

$$St^2D/6 = \tfrac{1}{4}A'Pw$$

ence $$t = \sqrt{3\,A'Pw/2\,SD}$$

ich becomes for $S = 3\,000$

$$t = 0.0224\sqrt{A'Pw/D}$$

d for $$S = 16\,000$$

$$t = 0.0097\sqrt{A'Pw/D}$$

Example 4. It is required to determine the size and thickness of a cast-iron ring-plate to be used under a wooden post 12 in square in cross-section and signed for a load of 115 200 lb. The plate is to be set on brickwork laid in ent mortar in New York. (See Table I.)

Solution. The required area of the base is 115 200/250 = 461 sq in. $\sqrt{461}$ 21.47 and a 22-in. square plate would be used.

Then
$$A' = 461 - 144 = 317 \text{ sq in}$$
$$P = (22 - 12)/2 = 5 \text{ in}$$
$$D = 12 \text{ in}$$
$$w = 250 \text{ lb per sq in}$$

nce $$t = 0.0224\sqrt{317 \times 5 \times 250/12} = 4 \text{ in}$$

This thickness may be beveled to 1½ in at the edge. The computed thickness greater than is usual for such plates, some formulas having more practical stants which really assume a stress of about 10 000 lb per sq in in cast iron bending.

If the plate is made of steel

$$t = 0.0097\sqrt{317 \times 5 \times 250/12} = 1\tfrac{3}{4} \text{ in}$$

2. Bearing-Brackets on Cast-Iron Columns

he Usual Column-Connections for fastening beams and girders to cast-i columns are shown in Fig. 7.* The end of the beam or girder is set on ELF P, under which is a BRACKET-SUPPORT C, cast on the side of the column. a single beam, one bracket is sufficient; for wide beams or girders there ld be two ribs. The ends of the beams are fastened to the column by ing to LUGS L, cast on the column above the bracket. Sometimes a column stened by bolts passing through the bottom flange of the beam and through shelf-plate. This connection greatly decreases the lateral stability of a ing and should not be used.

he Shelf and Brackets, when loaded, are subject to SHEARING and BEND-STRESSES. The SHEAR at the outer surface of the column-shell is equal e end-reaction of the beam it supports. The BENDING-STRESS is due to the cation of the load on the shelf-plate at some distance from the surface of lumn. It causes a tension at the top of the bracket which tends to tear e shell of the column, and causes, also, a compression at the foot of the The THICKNESS OF THE RIB must be great enough to withstand the com-n from the load above; and since the stress is variable along a section,

* See also, Figs. 5 and 7, pages 457 and 458.

as along the line X, a rough approximation may be made by assuming t stress at the extreme edge to be twice the average stress, and by further assu ing that the section in the rib takes care of all the compression. This make unnecessary to find the CENTER OF GRAVITY and the MOMENT OF INERTIA of t section at X, both of which must be known if the FLEXURE-FORMULA is us This procedure, also, makes unnecessary any assumption as to the true positi of the CENTER OF PRESSURE on the top surface of the bracket. With the thi ness of rib given in the tables there is an ample FACTOR OF SAFETY for any lo

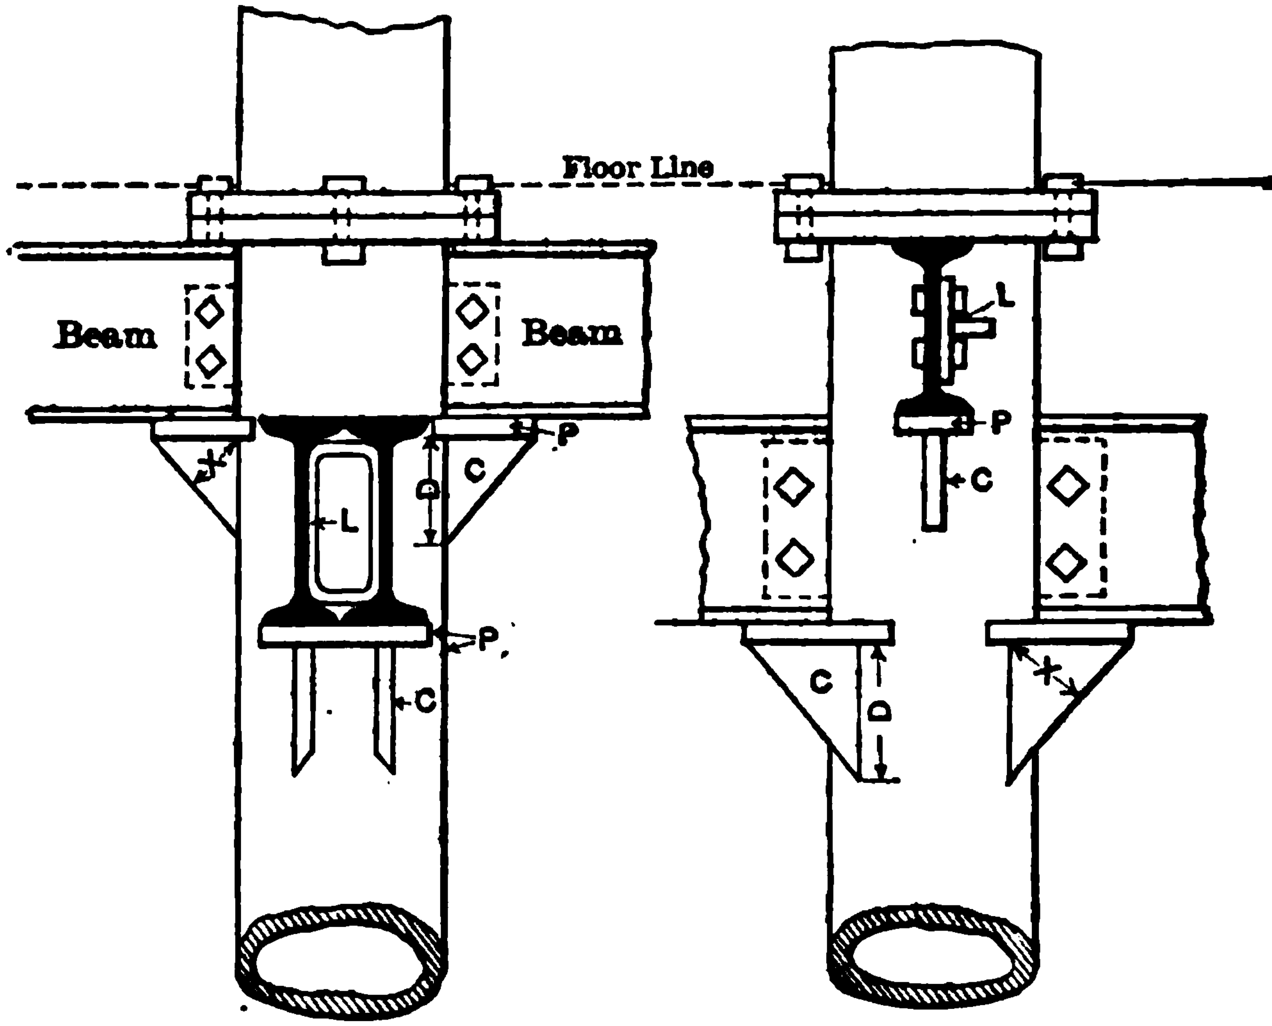

Fig. 7. Cast-iron Columns with Bearing-brackets

that may be applied through a beam. The double ribs are required when beams are used, not for strength, but to prevent the failure of the shelf ECCENTRIC LOADING.

Tests of Cast-Iron Brackets. Brackets of cast-iron columns tested by New York Building Department gave a SHEARING STRENGTH of 4 200 lb sq in on the section at the column when the load was applied at the end of bracket, and an average of 8 000 lb per sq in when the load was distributed the bracket-shelf. The RANGE OF STRESS in the first case was from 2 45 5 600 and in the second from 4 100 to 10 900 lb per sq in. In seventeen ou twenty-two tests the MANNER OF FAILURE was the tearing out of a hole in body of the column. It appears that when the thickness of the rib and is the same as that of the shell of the column, there is generally ample stre for the support of beams and girders; but that in the case of very he loaded beams, the SHEARING and CRUSHING STRENGTH should be investig From the results of the tests mentioned, a low WORKING STRESS FOR S must be assumed.

The Bevel of Brackets. If the shelf P (Fig. 7), on which the beam is cast SQUARE with the column, when the beam deflects, the load is broug the extreme end of the bracket, causing an increased bending-stress in

acket and connections and tending to tear a hole in the column-shell. T
oid this the bracket-shelf should be sloped downward, away from the colum
d should have a BEVEL of ⅛ in to the foot.

Standard Connections for Cast-Iron Columns. Table III, publishe
iginally in the Passaic Rolling Mill Handbook, and widely used by othe
anufacturers, will be found useful when detailing cast-iron columns.

Table III. Standard Connections for Cast-Iron Columns

CHAPTER XIV

STRENGTH OF COLUMNS, POSTS AND STRUTS

By
CHARLES P. WARREN
LATE ASSISTANT PROFESSOR OF ARCHITECTURE, COLUMBIA UNIVERSITY

1. General Principles and Definitions

Slenderness-Ratio. The manner in which a material fails under compre or pressure depends not only upon its nature, but also upon its dimension form. The ratio of its length, in inches, to its diameter or least lateral di sion, in inches, l/d, or the ratio of its length to its least radius of gyratio is its SLENDERNESS-RATIO.

The following average limits of slenderness-ratios are generally recog in engineering practice:

Solid wooden columns, l/d from about 8 to 30;
Solid wooden columns, l/r from about 30 to 100;
Hollow cast-iron columns, l/d from about 8 to 20;
Hollow cast-iron columns, l/r from about 10 to 70;
Steel columns, l/r from about 30 to 150.

Three Classes of Columns. (1) The actual compressive strength of terial must be determined on very short specimens in which there is no ten to bend or to buckle. (2) The load required to break the specimen do change much until l/d is about 8 or 10, or l/r is about 25 or 30. When ratios are exceeded, the specimens tend to fail partly by direct compressio partly by bending. (3) When l/r is greater than about 200, the colum by bending.

2. Strength of Short Wooden Columns

The Safe Load for a Short Wooden Column, the length of which more than 10 times the least dimension, may be computed by the formula

$$\text{Safe load} = \frac{\text{area of cross-section} \times S}{\text{factor of safety}}$$

in which S denotes the crushing strength of the given material as stat Table I.

The Factor of Safety to be selected depends upon the place where th umn is used, the load which comes upon it, the quality of the material an large measure, upon the value given to S. For lumber of ordinary quality taining no very bad knots, a FACTOR OF SAFETY of five may be used; or, in words, the safe stress per square inch of section-area may be taken as on of the values given in Table I. If the column is badly season-checked, grained, or contains bad knots, a larger factor, say six or seven, should be The character of the load, also, should be taken into consideration in deter the factor of safety. Thus for a wooden post supporting a brick wall a factor should be used than for one supporting a floor, as in the former ca full load is at all times on the post, and the least reduction of its section-

of fire might cause it to give way. Wooden posts supporting machinery, or ...den struts in railway bridges, should have a factor of safety of from six to ...it, if the values of S given in Table I are used.

...ble I.* Average Crushing-Loads in Pounds per Square Inch, for Building Materials

Materials	Crushing-loads, lb per sq in	Materials	Crushing-loads, lb per sq in
	S		S
...r stone, brick, concrete ...and masonry, see Chapter V		Woods (continued)	
		Cypress	3 500
		Hemlock	4 000
Metals		Oak, white	5 000
		Pine, long-leaf yellow	5 000
...ast iron	80 000	Pine, short-leaf yellow	4 000
...rought iron	55 000	Douglas fir	4 500
...teel, rolled shapes	60 000	Pine, Norway	3 500
		Pine, white	4 000
Woods, with the grain†		Redwood, California	4 000
...edar	3 500	Spruce	4 500
...hestnut	4 000	Whitewood	3 000

* See, also, Table XVI, page 647, and Table I, page 1138.

† These are values for wooden columns under 15 diameters in height and are, of ...e, average values. For the safe loads, per sq in, on timbers, perpendicular to ...grain, see Table VI.

...ample 1. What is the safe load for a long-leaf yellow-pine column, 10 by 10 ...n cross-section and 12 ft long, using a factor of safety of 5?

...ution. Area of cross-section = 100 sq in; safe load per sq in = 5 000/5 = 1000; ...0 × 100 = 100 000 lb.

...ample 2. It is required to support a brick wall weighing 80 000 lb by a ...uglas-fir column 11 ft long. What should be the cross-section of the column?

...lution. As previously stated, for these conditions it would be wise to use a ...or of safety of 6. Then the safe resistance per square inch of section-area = ...0/6 = 750; 80 000/750 = 106 sq in required, about equivalent to a 10 by ...n cross-section.

. Strength of Wooden Columns or Struts Over Ten Diameters in Length. Formulas

...ormulas for Wooden Columns. If the length of a solid column exceeds ...t ten times its least cross-dimension it is liable to bend under the load, and ...ce to break under a less load than would break it if it were shorter and of ...same cross-section. To deduce a formula which will make the proper allowance for the length of a column has been the aim of many engineers, but their ...ulas have not always been exactly verified by actual results.

...ntil recently the formulas of Lewis Gordon and C. Shaler Smith have been ... generally by engineers, but the extensive series of tests made by the Govern...t at Watertown, Mass., on full-sized wooden columns, showed that these ...ulas did not agree with the results there obtained. James H. Stanwood ...e year 1891 plotted the values of all the tests made at the Watertown ...enal up to date on full-size wooden columns. From the results thus obtained

he deduced the following STRAIGHT-LINE FORMULA for long-leaf yellow-pine ε white-oak columns:

$$\text{Safe load per square inch} = 1\,000 - 10 \times \frac{\text{length in inches}}{\text{breadth in inches}}$$

The author has carefully compared this formula with the results of act tests, and with other formulas,* and believes that for timber without seri defects and with not more than 10 or 12% of moisture, it meets the actual c ditions as nearly as any other formula. He has therefore prepared Table III, IV and V for the strength of round and square columns of the sizes gener used in practice. Of course other formulas must be used when required by tain city building laws. For other sizes the loads can easily be computed the formulas. For columns having bad knots or other defects, or more t 10 or 12% of moisture, or which are to be exposed to the weather or known be eccentrically loaded, a deduction of from 10 to 25% should be made from values given in the tables.

The loads for columns of other species of wood were computed by the follow formulas of the same form as that of Formula (2):

For Douglas fir and spruce,

$$\text{Safe load per square inch} = 850 - 8.5 \times \frac{\text{length in inches}}{\text{breadth in inches}}$$

For chestnut, hemlock, short-leaf yellow pine and white pine,

$$\text{Safe load per square inch} = 750 - 7.5 \times \frac{\text{length in inches}}{\text{breadth in inches}}$$

For cedar, cypress, redwood, Norway pine and whitewood,

$$\text{Safe load per square inch} = 625 - 6 \times \frac{\text{length in inches}}{\text{breadth in inches}}$$

In these formulas the breadth is the least side of a rectangular column, or diameter of a round column. The round columns were computed for the inch, to allow for being turned out of a square column, of the next size la The formulas were used only for columns with a diameter or least side exc ing 12 diameters for yellow pine and white oak, and exceeding 10 diam for other woods.

4. Tables of Safe Loads for Wooden Columns

Tables II, III, IV and V give the safe loads in pounds for round and sc wooden columns of different cross-sections and lengths and of different kin wood. They were computed from formulas as explained above and ar favorable conditions of material, seasoning and position in buildings.

* There are many formulas for the safe loads per square inch of cross-section of w columns. Among those frequently used are the following:

American Railway Engineering and Maintenance of Way Association,

$$P/A = S\,(1 - l/60\,d)$$

Department of Agriculture,

$$P/A = S\,(700 + 15\,l/d)/(700 + 15\,l/d + l^2/d^2)$$

Winslow Formula (Chicago Law),

$$P/A = S\,(1 - l/80\,d)$$

In these formulas, P is the safe load in pounds, A the area of the cross-section in inches, P/A the safe load in pounds per square inch, S the safe end-bearing comp per square inch, l the length in inches and d the least side or diameter in inches. formulas give smaller safe loads than those of Tables II, III, IV and V; but as th of these tables are to be DECREASED for unfavorable conditions and the loads dete from the three formulas mentioned INCREASED for favorable conditions, the resu about the same.

8. Eccentric Loading of Wooden Columns

eneral Principles. When the load on a short column or post is not axial, t is, when the column supports a girder on one side only, or when the weight n one girder is much more than that from the others, the load is said to be ntric, and the distance from the point of application of the load to the axis he column, denoted by p, is called the ECCENTRICITY of the load. It is evi- t that the stress in the column will increase with p, and that the total unit s S, on the side of the column in which the pression is the greatest, will be greater than for equal axial load.

mula for Eccentric Load. Suppose the ntric load to be applied as shown in Fig. 1, n the sectional area of the required square or ngular column may be computed by the fol- ing formula (See, also, page 486):

he sectional area of the column in square hes is

$$A = (P + P_1)/S + 6\,P_1 p/Sd \qquad (6)$$

hich A = sectional area in square inches
P = concentric load on column in pounds
P_1 = eccentric load in pounds
S = safe stress in pounds per square inch
p = distance from axis of column to center of bearing in inches
d = side of column parallel with girder, in inches

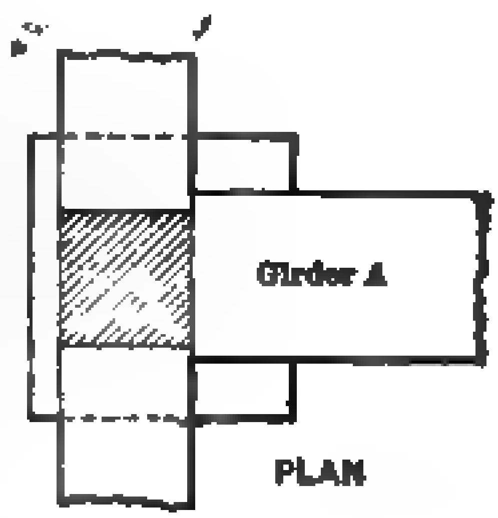

Fig. 1. Eccentric Load on Wooden Column

ssuming the value of S, the probable ratio of ide to the length of the column should be taken account. Thus if it is probable that the length not exceed 12 times the side, both being sured in inches, for oak, long-leaf yellow-pine or glas-fir columns, or 10 times the side for other ds, then the value of S for short columns may taken. If the ratio will probably be greater this, then the probable ratio should be roughly mated and S computed for that ratio by the ula given for columns more than 10 or 12 diameters in length, as noted in eding paragraphs.

mple 3. The lower post in Fig 1 supports a total load on its cap-plate 000 lb, including the reaction of 12 000 lb from girder A What should be ize of the column if made of Douglas fir and if 12 ft in height?

ution. As it is probable that the column will have to be 10 in square S may aken from Table I. With a factor of safety of 5, this is equal to 4 500/5 = lb per sq in. P_1 = 12 000 lb, d = 10 in and p, the distance from the axis of column to the center of bearing of the girder = 7 in. Then from Formula (6), sectional area of the column is

$$A = \frac{60\,000}{900} + \frac{6 \times 12\,000 \times 7}{900 \times 10} = 66.6 + 56 = 122.6 \text{ sq in,}$$

equivalent to a 12 by 12-in square column. From Table III, it may be that an 8 by 10-in column concentrically loaded will carry almost 60 000 lb.

Hence, the eccentric load from the girder increases the dimensions of the cro
section of the column from 8 by 10 to 12 by 12 in.

For wooden columns having a length of over 12 diameters for Douglas fir a
spruce and over 10 diameters for other woods the safe load per square i
should be found by using Formulas (3), (4) or (5).

Example 4. What size will be required for a white-oak column, 14 ft in len
to carry a total load of 56 000 lb, 16 000 lb of which act as an eccentric load fr
a girder, the distance from the center of bearing of the girder to the column be
2 in.

Solution. From Table II, it is probable that at least a 10 by 10-in colu
will be required, so that S must be calculated by Formula (2).

$$S = 1\,000 - 10 \times \frac{\text{length in in}}{\text{breadth in in}}$$

Substituting,
$$S = 1\,000 - 10 \times \frac{168}{10} = 832 \text{ lb per sq in}$$

Substituting in Formula (6),

$$A = \frac{56\,000}{832} + \frac{6 \times 16\,000 \times 7}{832 \times 10} = 68 + 80 = 148 \text{ sq in}$$

equivalent to a 12 by 12-in column.

6. Metal Caps and Bolsters for Wooden Columns

Use of Metal Post-Caps. Whenever wooden posts are used in tiers,
above another, each post except the top one should have an iron cap-p
and the upper post should be set on the cap of the post below and not o
girder. Where a wooden post supports a girder, only, a wooden bolster ma
used in place of the cap but modern approved metal post-caps are always
erable to wooden bolsters. Details of post-caps and bolsters are show
Chapter XXII.

7. Crushing of Wood Perpendicular to the Grain

Safe Unit Stresses. The bearing of wooden girders, the ends of col
resting on girders, and washers on truss-rods, should be proportioned so
the quotient obtained by dividing the load by the bearing area will not e
the safe unit stresses given in Table VI.

Table VI. Safe Loads for Wood Perpendicular to the Grain

Kind of wood	Safe loads, lb per sq in	Kind of wood	Saf loa lb per
White oak	500	Cedar	2
Long-leaf yellow pine	350	Spruce	2
Douglas fir	200	Hemlock	1
Norway pine	200	Cypress	2
White pine	200	Redwood	1
Short-leaf yellow pine	250	Chestnut	2

8. Cast-Iron Columns*

Cast-Iron Versus Steel Columns. Although steel is being used more and more every year for columns in buildings, it will probably never entirely supplant cast iron for buildings of moderate height. For skeleton construction, however, when the height of the building exceeds twice its width, riveted steel columns, with riveted connections with the beams and girders, are unquestionably better; but for the larger proportion of buildings of moderate height, cast iron will probably have the preference for some time to come because it is more economical.

Advantages of Cast-Iron Columns. The commercial advantages which favor the use of cast-iron columns are these:

(1) **Cheapness.** As far as the cost of production is concerned, cast iron is cheaper than steel. This consideration alone often decides in favor of its employment. The raw material is easily transported as pig iron is sometimes brought over as ballast; so that competition with foreign countries keeps down the price.

(2) **Availability.** Cast iron is the most available form of iron. An iron-foundry requires no very elaborate plant, scarcely more than a few furnaces and sand molds, and moreover, no very extensive capital is required to operate it; consequently, the product may be obtained in almost any locality. In rolling-mills, on the contrary, the machinery must be very heavy in order that it may overcome the enormous pressure due to the resistance of the steel in rolling, and to operate it requires a great amount of power.

(3) **Readiness with Which it May be Obtained.** Columns and other structural members if made of cast iron may be obtained much more quickly than if made of steel. After the pattern has once been prepared, a dozen castings may be made almost as quickly as one, and with but very little extra cost, except that of the additional raw material and the expense of remelting it. On the other hand, columns and girders built up of rolled sections take considerably longer to make. Sections can be punched only one at a time, and if they do not happen to be of some standard length, they must be cut and fitted separately before all can be finally riveted together.

(4) **Physical Advantages.** Cast iron is one of the best materials to resist compression, its ultimate compressive strength being as high as 80 000 lb per sq in and even higher. Moreover, it can be molded into almost any desired form, and lugs, brackets and flanges may be cast upon a column all in one piece thus greatly simplifying the cost of erection. In fact, the ease with which the beam and girder-connections can be made is one of the chief reasons for the popularity of cast iron. Finally, it resists fire better than steel and it corrodes less easily. Because of this, its use is advocated by many for the wall columns of skeleton structures, as these columns are particularly liable to corrode. In the Mutual and Manhattan Life Insurance Company's Buildings in New York City, for example, the wall columns are of cast iron, whereas the interior ones are of steel.

Disadvantages of Cast-Iron Columns. The disadvantages of cast iron for columns are as follows:

(1) **Physical Disadvantages.** Cast iron is hard and brittle and cannot be punched or riveted, as the blows required in driving the rivets would very likely fracture the castings; consequently, all connections have to be made with bolts. A bolted connection even under the most favorable conditions is not very rigid,

* See, also, Chapter XIII, pages 445 to 447.

as it allows more or less lateral movement, which, in the case of a tall, nar building, is a serious matter. Owing to the low tensile and shearing strength cast iron, the brackets supporting beams and girders are unreliable and requ great skill in designing. (See pages 445 to 447.)

(2) **Defects in the Castings and the Difficulties of Thorough Inspection.** T castings themselves are subject to a number of serious defects. In the first pl owing to the shifting or floating of the cores, variations in the thickness of hol castings are not infrequent; in fact, it is very difficult to avoid them even w the best care and workmanship. Moreover, there are apt to be concea cavities, blow-holes or honeycomb, and foreign substances, such as cinders sand, any of which may be on the inside of a casting, where a careful exami tion often fails to reveal them. The most critical condition, however, is t due to the uneven contraction of the metal during the process of cooling, thin parts of the casting cooling and contracting more quickly than the th ones, thereby giving rise to INITIAL STRESSES, at times of sufficient inten to fracture the casting before any external loads whatever have been plac upon it. In many cases this trouble is due to faulty designing or to carelessn in handling the molds; yet, even under the most favorable conditions, it is difficult to secure equal radiation from the molds in all directions that castin entirely free from inherent shrinkage-stresses are probably seldom produced

9. Design of Cast-Iron Columns

Common Forms of Cast-Iron Columns. Figs. 2, 3 and 4 show so common forms of cross-sections of cast-iron columns. Columns of circular rectangular cross-sections are always made hollow and the diameter should made as large as possible, within reason of course; because of two colum

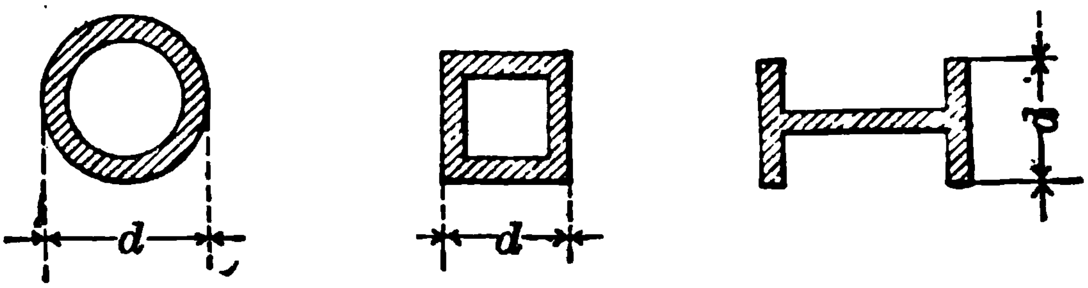

Fig. 2 Fig. 3 Fig. 4

Figs. 2, 3 and 4. Cross-sections of Cast-iron Columns

having the same area of cross-section, the one which, within certain limits, the greater diameter, and consequently the thinner shell, is the stronger. T maximum thickness of shell is 1¾ or 2 in, because of the difficulty of keep the core from shifting in columns of greater thickness; and the minimum thi ness is ¾ in. The latter is a requirement of most municipal building co As the maximum limit of diameter, 16 in may be taken; beyond this, built steel columns can be used to better advantage and are less expensive. T minimum diameter permitted by most building codes is 5 in, and the unsuppor length of the column is limited to 20 times the least diameter.

Hollow, Cylindrical Cast-Iron Columns. The most economical form cross-section, as far as structural requirements are concerned, is the HOLL CIRCLE (Fig. 2). This form is generally used for interior columns; but for terior columns it is not so desirable, because such columns cannot be bonded walls so readily, and do not present the same facilities for the design of the b and girder-connections as columns having the other forms of cross-secti

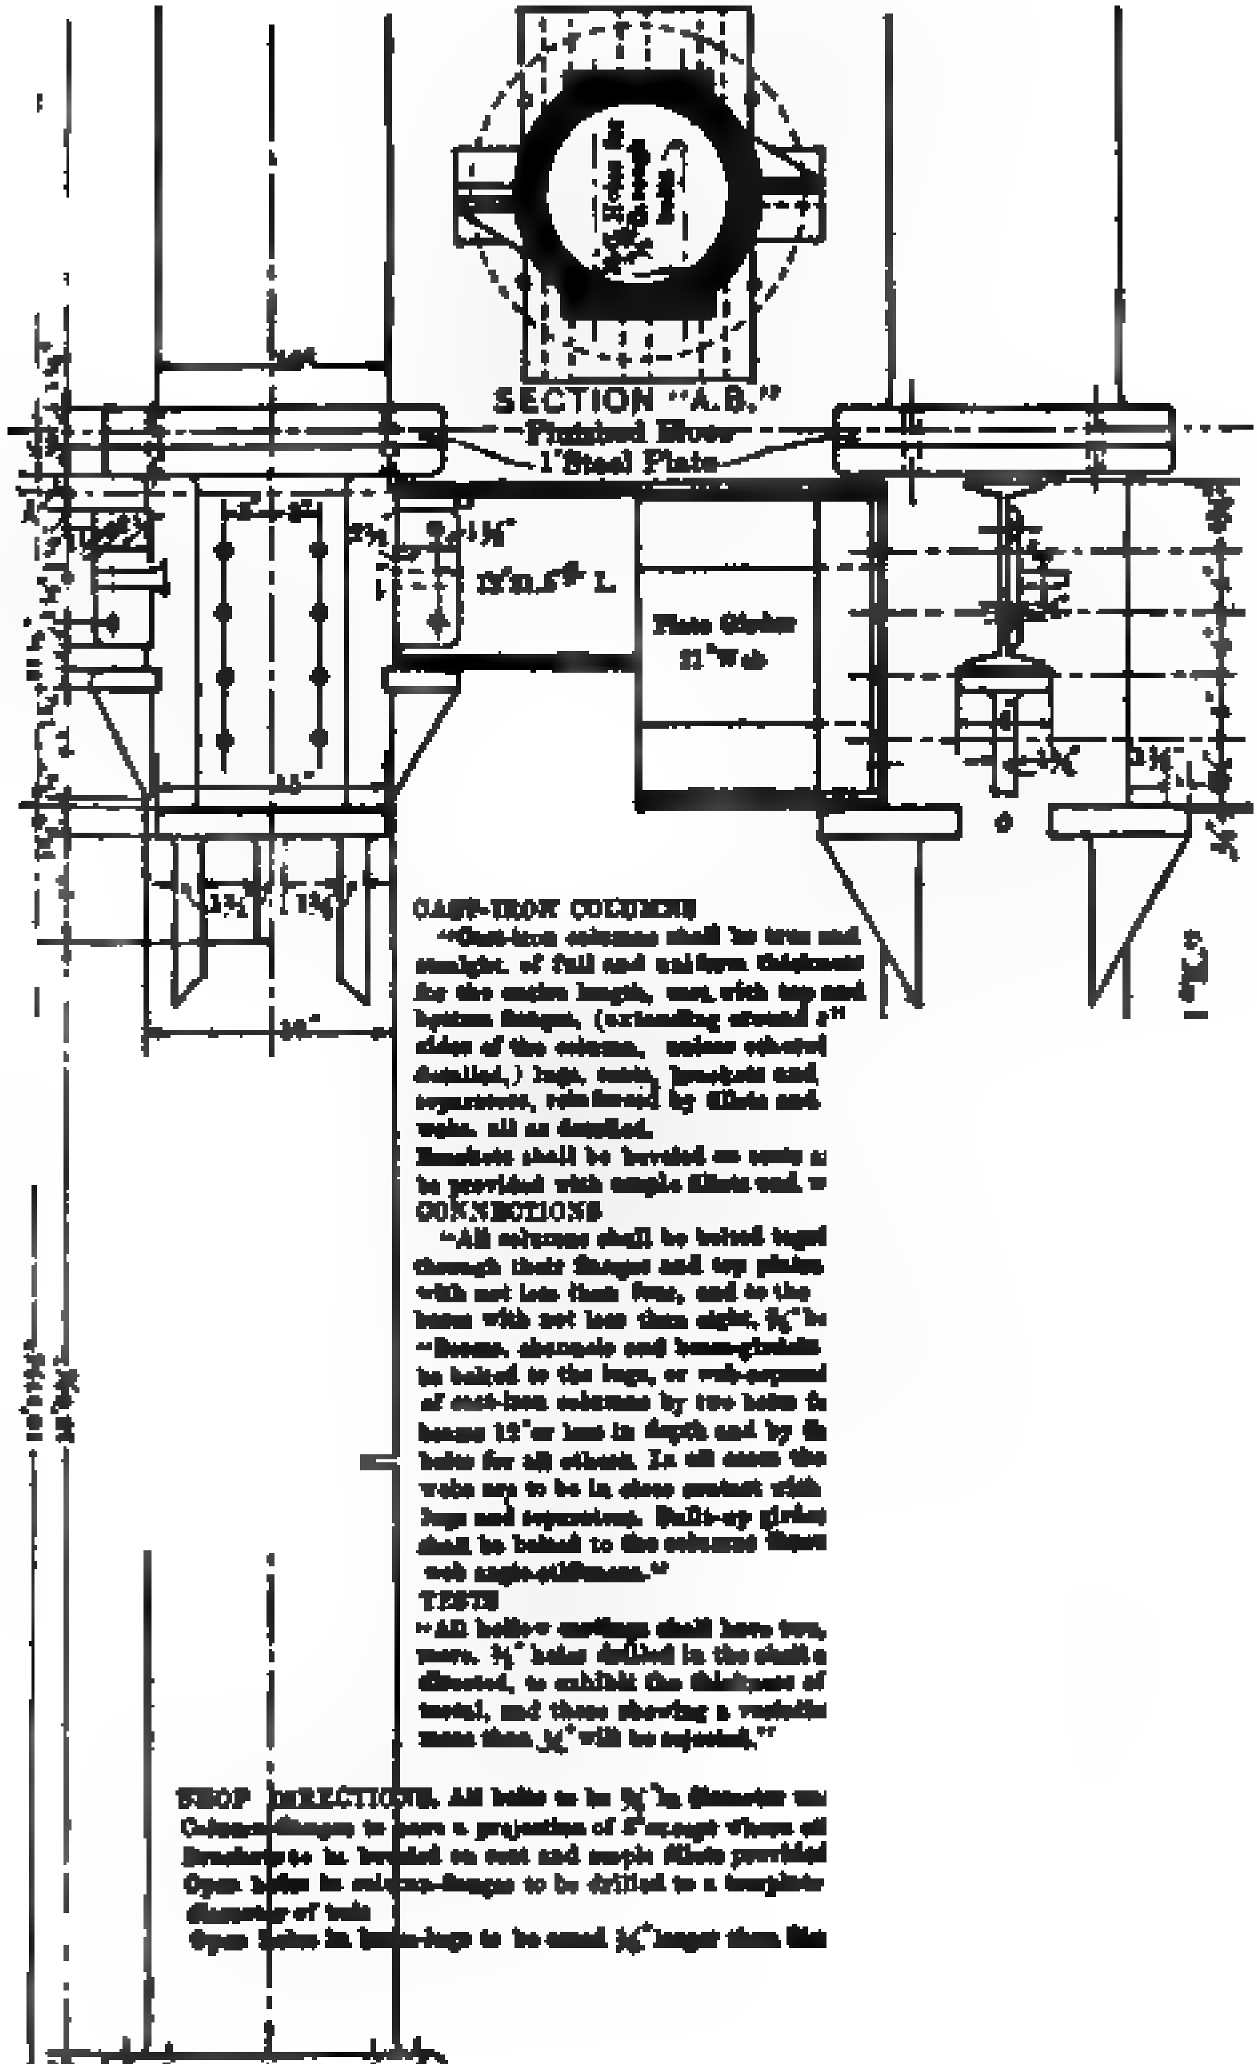

Fig. 5. Connections for Cylindrical Cast-iron Columns

Typical Connections for a Cylindrical Cast-Iron Column. Fig. 5 ... details of a cylindrical cast-iron column with typical beam and girde... ...ctions, dimensions and specification-notes. (See, also, details of connec... ...ackets, base-plates, etc., for cylindrical columns in Chapter XIII, Figs ... 7 and Table III of same chapter.)

Cast-Iron Columns with Hollow-Square Cross-Section. The colum next in point of economy of cross-section are tho with the HOLLOW-SQUARE cross-section (Fig ? They are generally used for wall columns becau it is easier to bond them into the masonry than they had a circular section. Columns of holl rectangular cross-section of unequal sides are som times found to be more available than those of squa section.

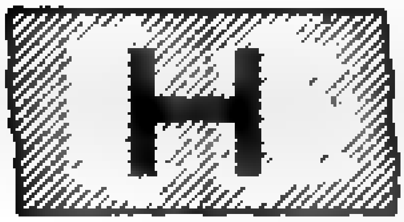

Fig. 6. H-shaped Cross-section of Cast-iron Column

The H-Shape Column (Fig. 4) ranks third regard to economy of material. It is particularly well adapted for wall colum in skeleton construction for the following reasons:

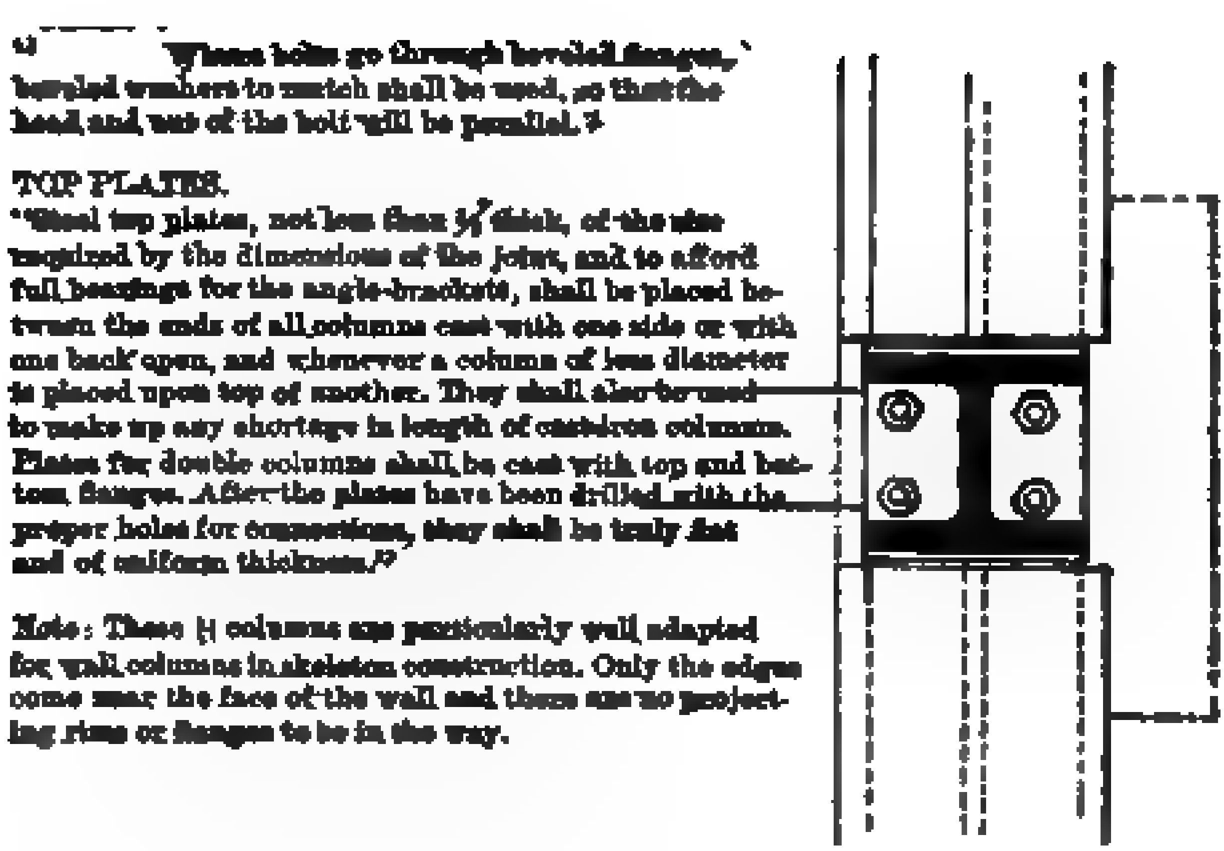

Fig. 7. Connections for H-shaped Cast-iron Column

(1) Being entirely open, with both the interior and exterior surfaces expo any inequalities in thickness can be readily discovered and the thickness is

ily measured, thus obviating any necessity for drilling, and rendering the spection of the columns much easier.

(2) The entire surface of the column may be protected by paint.

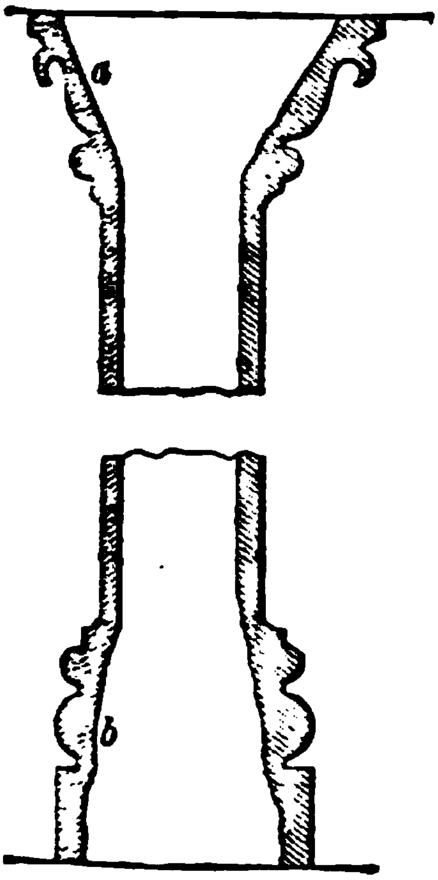
(3) When built in brick walls the masonry fills all voids, so that no open space left; and if the column is placed as shown in Fig. 6, only its edges come near e face of the wall.

(4) Lugs and brackets can be cast on such columns more readily and effectively an on cylindrical columns, especially for wide and heavy girders, and the nections do not require projecting flanges, which are often in the way on lindrical columns.

(5) An eccentric load may be applied to the web where its effect is less and here it is more evenly distributed than when it is applied to the outer rim or ell.

Details of connections and brackets for H-shaped cast-iron columns are shown Fig. 7.

Details of Connections of Cast-Iron Columns. The bearings of a cast-iron column should always be faced true to the axis of the column, and the columns should be bolted together by four ¾-in bolts for columns 10 in in diameter or less, and by six bolts for 12-in and larger columns. Faced plates, as shown in Fig. 5, are inserted between the flanges of columns to make up for any shortage in length and also when a column of smaller diameter is placed over one of greater diameter. For convenience in erecting columns, the joint is generally placed just above the beams or girders supported by the columns.



g. 8. Cast-iron Column with ap and Base. Wrong Method

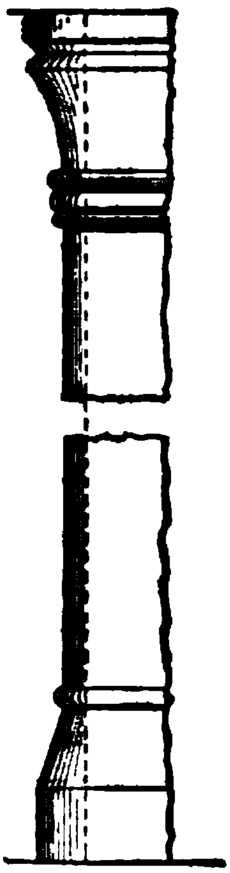


Fig. 9. Cast-iron Column with Cap and Base. Slight Projections

Projecting Caps and Bases. A column with ornamental cap and base should ver be cast as shown in Fig. 8, that is, if it is to support load. In every bearing column, the core should extend a straight line from end to end. Plain molded caps and bases may be cast id as in Fig. 9; but if more ornamental caps are desired, or heavy projecting es, they should be cast separately and attached to the straight columns by ews.

10. Strength of Cast-Iron Columns. Formulas

Formulas for Cast-Iron Columns. The ULTIMATE RESISTANCE of cast iron crushing is generally taken at 80 000 lb per sq in, and for posts, pintels, etc., re the length is not more than six times the diameter or breadth, it will lly be safe to assume a WORKING STRENGTH of six tons per square inch of al. For longer posts or columns, the strength is affected by the ratio of

length to diameter, but to just what extent is not known with absolute certai hence all formulas for columns must be more or less theoretical. The co quence is that while a great many formulas have been published, there is that is universally accepted. The two following Formulas * (7) and (8), for many years more commonly adopted than any others, as they appear agree as well as any with actual tests.

Formula for Hollow, Cylindrical, Cast-Iron Columns with Square End Ultimate strength, in pounds.

$$= \text{metal-area} \times \left[80\,000 + \left(1 + \frac{\text{sq of length in in}}{800 \times \text{sq of diam in in}} \right) \right]$$

or

$$\text{Ultimate strength, in pounds} = \frac{80\,000\,A}{1 + l^2/800\,d^2}$$

in which A is the area of the cross-section in square inches.

* The tables in the handbook of the Cambria Steel Company (1913) are ba Formulas (7) and (8), and they were adopted in some building laws. They are base the form of Gordon's formula, which, in turn, is Rankine's formula with d, the di or least lateral dimension, substituted for r, the least radius of gyration of the cro tion. Rankine's formula is sometimes referred to as Gordon's formula. The obtained by these formulas will be slightly in excess of those given in the old C building law (see tabulation in this foot-note), and considerably less than those per by the former building law of New York City, $S = 11\,300 - 30\,l/r$. (Present $S = 9\,000 - 40\,l/r$.

In 1898 Professor W. H. Burr made an analysis of the results of a number of ments on full-size, hollow, cylindrical cast-iron columns made at the Watertown A Mass., and at Phœnixville, Pa., and by plotting the results found that a straig formula having the equation $S = 30\,500 - 160\,l/d$, in which S is the ultimate st of the metal per square inch of column-area, represented the average of the results. With a factor of safety of 4 this would become $S = 7\,625 - 40\,l/d$ and factor of safety of 5, $S = 6\,100 - 32\,l/d$.

According to Professor Burr's analysis the values for S given in the fourth col Table VII represent a factor of safety of a little over 4 for $l/d = 20$, and of near $l/d = 36$.

Formulas for finding the value of S according to the former codes of Chicago and

Cylindrical columns		Rectangular columns	
Old Chicago Code	Old Boston Code	Old Chicago Code	Old Boston
$\dfrac{10\,000}{1 + \dfrac{l^2}{600\,d^2}}$	$\dfrac{10\,000}{1 + \dfrac{l^2}{800\,d^2}}$	$\dfrac{10\,000}{1 + \dfrac{l^2}{800\,d^2}}$	$\dfrac{10\,000}{1 + \dfrac{l^2}{1066}}$

The former New York City Building Code Formula was

$$S = 11\,300 - 30\,l/r$$

Compared with the results of tests that have been made on full-size cast-iron col has been shown that while in Chicago a factor of safety of 8 was allowed, the actu of safety was a little over 4, that in Boston it was slightly under 4, while in New was a trifle over 6. The formula in the new (1916) Chicago code is $S = 10\,000 -$ while the new (1915) Boston code gives the values of S for l/r from 10 to 70.

A series of tests on full-size cast-iron columns and brackets was made under th tion of Stevenson Constable, in December, 1897, a report of which, with illust may be found in the Engineering Record for January 8 and 22, 1898.

Formula for Hollow, Rectangular, Cast-Iron Columns with Square Ends

imate strength, in pounds

$$= \text{metal-area} \times \left[80\,000 \div \left(1 + \frac{\text{sq of length in in}}{1\,067 \times \text{sq of least side in in}}\right)\right] \quad (8)$$

$$\text{Ultimate strength, in pounds} = \frac{80\,000\,A}{1 + l^2/1\,067\,d^2}$$

hich A is the area of the cross-section in square inches

Formula for Solid, Cylindrical, Cast-Iron Columns

imate strength, in pounds

$$= \text{metal-area} \times \left[80\,000 \div 1 + \frac{\text{sq of length in in}}{266 \times \text{sq of diam in in}}\right] \quad (9)$$

$$\text{Ultimate strength, in pounds} = \frac{80\,000\,A}{1 + l^2/266\,d^2}$$

hich A is the area of the cross-section in square inches.

For H-shaped columns use formula (7), taking d as the least side.

The SAFE LOAD is generally taken at one-eighth of the ultimate strength or aking-load.

ccentric Loading. Cast-iron columns should not be loaded with a heavy, NTRIC LOAD, that is, a load applied on one side of the column without a responding load on the other side, as cast iron is unable to resist very great ding stresses. (See, also, eccentric loading of wooden and steel columns, es 453 and 485.)

11. Tables of Safe Loads for Cast-Iron Columns. Examples

xplanation of Tables. As the allowable pressure PER SQUARE INCH OF AL depends upon the ratio of length to diameter, without regard to actual ensions (that is, it would be the same for a column 6 in in diameter and 12 ft g as for one 8 in in diameter and 16 ft long), it is practicable to prepare a e which will give the value of the terms of Formulas (7) and (8) inclosed in ckets for all ratios of diameter to length, and thus simplify very much the putation for any particular column. Table VII has been computed by ns of Formulas (7) and (8) for ratios of length to diameter varying from 8 6, and the same result will be obtained by using the values given in this e as by using the corresponding formula. To use this table it is only neces- to divide the length of the column by the least thickness or diameter, both ches, and opposite the number in the first column of the table coming nearest e quotient, find the SAFE STRENGTH PER SQUARE INCH for the column. load is multiplied by the METAL-AREA in the cross-section of the column the result is the SAFE LOAD for the column. Examples (5) and (6) will illus- the use of Tables VII to X.

ample 5. What is the safe load for a 10-in hollow, cylindrical cast-iron n, 15 ft long, the shell being 1 in thick?

ution. In this case the ratio l/d, which is the length of the column divided e diameter, both in inches, is 18, and opposite 18 in Table VII the safe per square inch for a cylindrical column is found to be 7 117 lb. The metal- f the column, from the table of areas on pages 42 and 463, is equal to the f a 10-in circle minus the area of an 8-in circle, or, 78.53 − 50.26 = 28.27 Multiplying these two together, for the safe load of the column the result 7 sq in × 7 117 lb per sq in = 201 917 lb, or about 100.5 tons.

Tables VIII, IX and X. To still further facilitate computations, Tabl VIII, IX and X, have been prepared, which give at a glance the safe loa based on a factor of safety of 8, for columns of the more common sizes a lengths. For lengths between those given in the tables sufficiently accura results may be obtained by interpolation. For any other factor of safet multiply the safe load given in the table by 8, and divide by the new fac of safety.

Example 6. What is the safe load for a 9-in hollow, cast-iron column square cross-section 12 ft long, the shell being 1 in thick?

Solution. From Table IX, the safe load is 129 tons. The same result m be obtained by using Table VII. The ratio l/d in this case is $144/9 = 16$ a the corresponding safe load in pounds per square inch is 8 064. The area the column is 32 sq in. Hence, the safe load is 32 sq in × 8 064 lb per sq in 258 048 lb, or 129 tons, which agrees with the safe load given in Table IX the same column.

Table VII. Breaking-Loads and Safe Loads in Pounds per Square Inch for Hollow, Cylindrical and Hollow, Rectangular, Cast-Iron Columns

Calculated by Formulas (7) and (8)

Length in inches divided by external breadth or diameter	Breaking-weight in pounds per square inch		Safe loads in pounds per square inch. Safety-factor 8

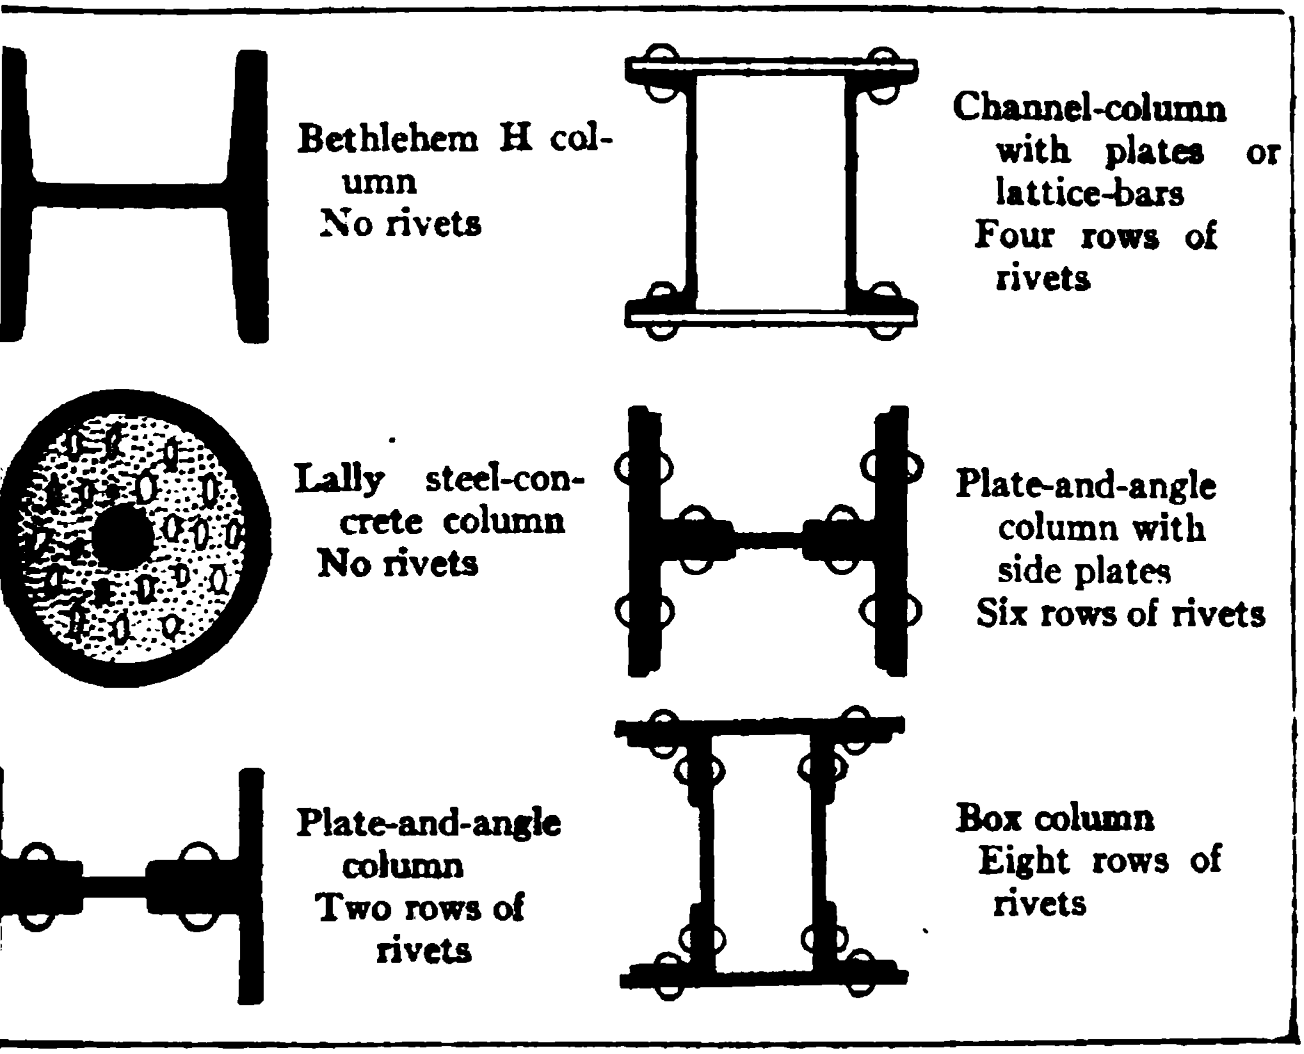
12. Types, Forms and Connections of Steel Columns

Use of Steel Columns, Struts, Trusses, etc. Owing to the many ad-
ntages of built-up steel columns over cast-iron columns, especially for all
ildings, and to the great reduction that has taken place in the cost of steel
nstruction, built-up columns are now very extensively used in buildings of
en moderate height; and for skeleton construction, or for buildings exceeding
x stories in height, they are certainly much to be preferred to cast-iron columns.
teel trusses, also, are now much more commonly used in buildings than in
rmer years, so that the architect must have at hand data for designing them
nd for computing their strength. In the following pages the author has en-
avored to cover the subject of columns and struts quite completely, to furnish
ch data as will enable the designer to decide upon the shape of column or
rut it is best to use, and also to determine the sizes and sections of such col-
mns with the least labor.

Types and Forms of Steel Columns. The following are cross-sections
f the majority of steel columns in general use, arranged in the order of their sim-
licity of construction, that is, the number of rows of rivets they require:



Considerations Governing the Selection of Steel Columns. There are
nsiderations other than simplicity of construction which sometimes govern
e selection of a column. Some of the most important of these are explained
the following paragraphs:

(1) Cost and Availability of Material. I beams, channels, plates and angles
the most common commercial sections. They are easily rolled and are
nufactured by all of the large mills. They are reasonable in price and may
obtained promptly in large numbers in any locality where a steel building is
ly to be erected. Patented sections, or the product of one mill, do not, as
le, fulfill these conditions.

(2) **Amount of Labor Required and Facility With Which it can be Performed i Shop and Field.** In the shop the complexity of the column-section and th number of pieces of which it is composed greatly affect the cost of labor. there are numerous small pieces such as lattice-bars, splice-plates, etc., eac of which requires cutting and fitting together, with frequent handling, the co is proportionately great. The cost of a column depends, also, largely upon th number of rivets required and whether they can all be driven by machine s as to avoid the slower and more expensive hand-riveting. The same gener remarks apply to labor in the field; the connections should be as simple a possible, the rivets easy of access and as few in number as is consistent wit strength.

(3) **Simplicity of Connections Between Column and Supported Member** This is quite an important consideration in the design of a large building an sometimes governs the choice of the section to be used. Where there are fo beams to a column, on opposite sides, and all of the same height, a satisfacto connection can be made with almost any section; but where the beams a spaced irregularly, both in regard to position in plan and to height, and whe eccentric loads must be provided for, it is very important that the section the column itself affords as great an opportunity as possible for the connectio of the beams. In this respect, possibly, closed sections are inferior to op sections having a central web.

(4) **Adaptability to Connections Which Transfer Compressive Stress Directly to Axis of Column.** In this respect, also, sections of an open constru tion, in which the girders transmit their loads almost directly to the centr axis of the column, thus avoiding the disadvantage of eccentric loading, a superior to those of a closed construction.

(5) **Adaptability to Changes in Thickness of Metal in Members of Column to Suit Different Loads in Different Stories.** It is not desirable to make t columns carrying the upper floors of a building very small, since the beams a girders supporting the upper floors are usually of the same dimensions as tho of the lower floors and consequently require just as heavy and secure conne tions. It is almost impossible to make such connections with small column and consequently, in order to reduce the area of a column in proportion to lighter load to be carried, it is better to reduce the thickness of the materi used and to keep the general dimensions of the section the same.

(6) **Adaptability to Fire-Proof Covering.** Closed sections in general can more compactly fireproofed than open sections.

General Considerations Affecting the Choice of Steel Columns. It almost impossible to say that any one of the foregoing types of steel colum is superior to the others. Each has its own good points, and the column wh section has theoretically the best distribution of material may not always the best one to use, because of the eccentric loads to be carried, or because other conditions. The choice in most cases will depend upon the personal vie of the designer, as well as upon the local conditions as to cost and manufactu promptness of delivery and the details of the problem. Further descripti of the different columns, and also the special advantages claimed for them, given in the following pages.

Steel-Column Connections. When steel columns were first designed it customary to use cap-plates to connect the story-lengths, and the beams girders often rested upon these plates. In modern practice, however, the umn-joint is generally placed just above the beams and girders for convenie in erection and the plates are often omitted The columns are closely fi

together with milled ends, and splice-plates are riveted to the sides or flanges as shown in the illustrations of typical steel-column details, Figs. 17 and 18. As it is impossible in these pages to include the subject of column-connections in anything but a general way, the only attempt that has been made in this direction is to illustrate common forms of connections that have been used with different kinds of columns. These will be found in the description of columns in the following pages.

Number of Rivets Required. No general rule can be given for the number of rivets and size of the brackets required for column-connections, as the loads to be supported vary in different buildings and in different parts of the same building. The number of rivets required in each connection must therefore be determined by the rules given in Chapter XII for designing riveted joints. Connections for single beams, however, will generally require the same number of rivets as are given for beam-connections (Chapter XV, page 617). The allowable stress for rivets in column-connections is generally taken at 10 000 lb per sq in for single shear and 18 000 or 20 000 lb per sq in for bearing. (See Tables II and III, pages 418 and 419, Chapter XII.)

Spacing of Rivets. Steel columns fail either by deflecting bodily out of a straight line or by the buckling of the metal between rivets or other points of support. Both actions may take place at the same time, but if the latter occurs alone, it may be an indication that the rivet-spacing or the thickness of the metal is insufficient. The rule has been deduced from actual experiments upon riveted columns that the distance between centers of rivets should not exceed, in the line of stress, sixteen times the thickness of metal of the parts joined, with a maximum spacing of 6 in, and that the distance between rivets or other points of support, at right-angles to the line of stress, should not exceed thirty-two times the thickness of the metal. The usual practice in designing columns is to space the rivets the minimum distance on centers at both ends, for a length equal to twice the least dimension of the column, with the maximum spacing of 6 in between.

Steel-Pipe Columns.* Steel-pipe columns are used for interior construction to carry beams and girders supporting floors, walls and chimneys in all classes of buildings, such as tenements and apartment-houses, factories, garages, churches, warehouses, etc. A particular demand for steel-pipe columns is at the angles of show-windows in mercantile buildings. In buildings of moderate height the floor-joists are usually supported by the side walls and the columns have to support only a relatively light wall above. For such places wrought-steel pipes may be advantageously used for the columns. They may be used, also, for the columns supporting the roof of one-story buildings. In the Borough of Brooklyn, New York City, pipe-columns were formerly calculated by the formula $S = 14\,000 - 80l/r$, in which S, l and r have values as explained below for New York and Chicago formula. If the columns are filled with concrete, the area of the cross-section of the concrete is multiplied by 500 and the product added to the load supported by the pipe. (See, also, page 477 and the Tables on page 476). This formula gave a factor of safety of four. New York and Chicago codes now use the formula, $S = 16\,000 - 70l/r$ in which S is the permissible unit fiber-stress, l the length in inches and r the radius of gyration of the cross-section of the pipe. This gives a carrying capacity greater than the former formulas gave. In Philadelphia, pipe-columns are allowed to carry

* Much valuable data relating to steel-pipe columns was furnished the editor-in-chief by P. C. Patterson and J. A. McCullough of the National Tube Company, Pittsburgh, Pa.

about 6% more than is allowed in New York. Where pipe-columns are fille with concrete the cast cap and base are secured to the pipe in each case by con crete which is reinforced internally by a pipe of smaller diameter. Whe

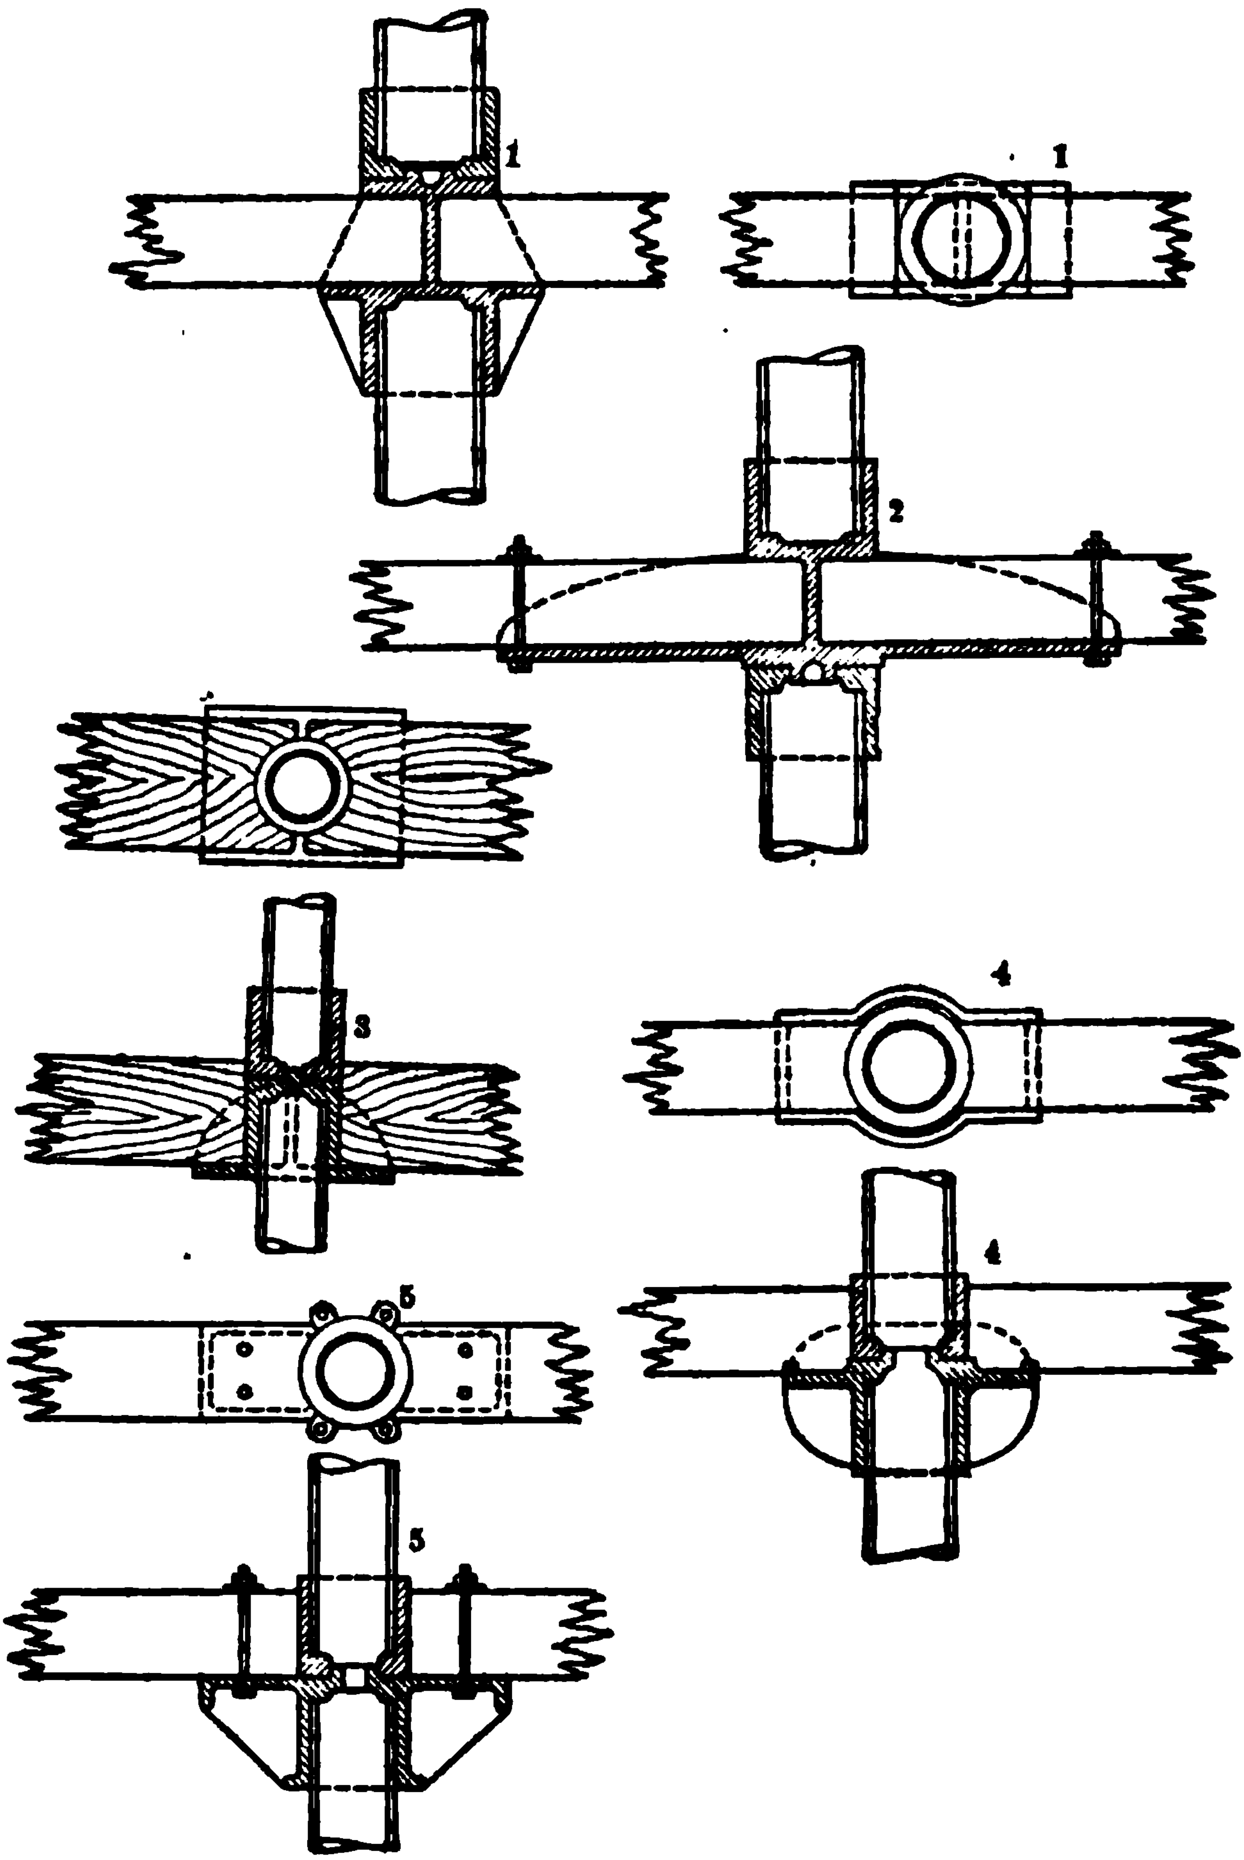


Fig. 10. Connections, Caps and Bases for Steel-pipe Columns

these steel-pipe columns filled with concrete are used, care should be t that the pipes are entirely filled, and that there are no air-spaces in the conc These concrete-filled columns, sometimes reinforced with smaller pipes,

a large carrying capacity. Pipe-columns may have their supporting power about doubled in many cases by concrete filling. (See, also, paragraph on Lally Columns, page 477). One type of steel post-cap used in connection with pipe.

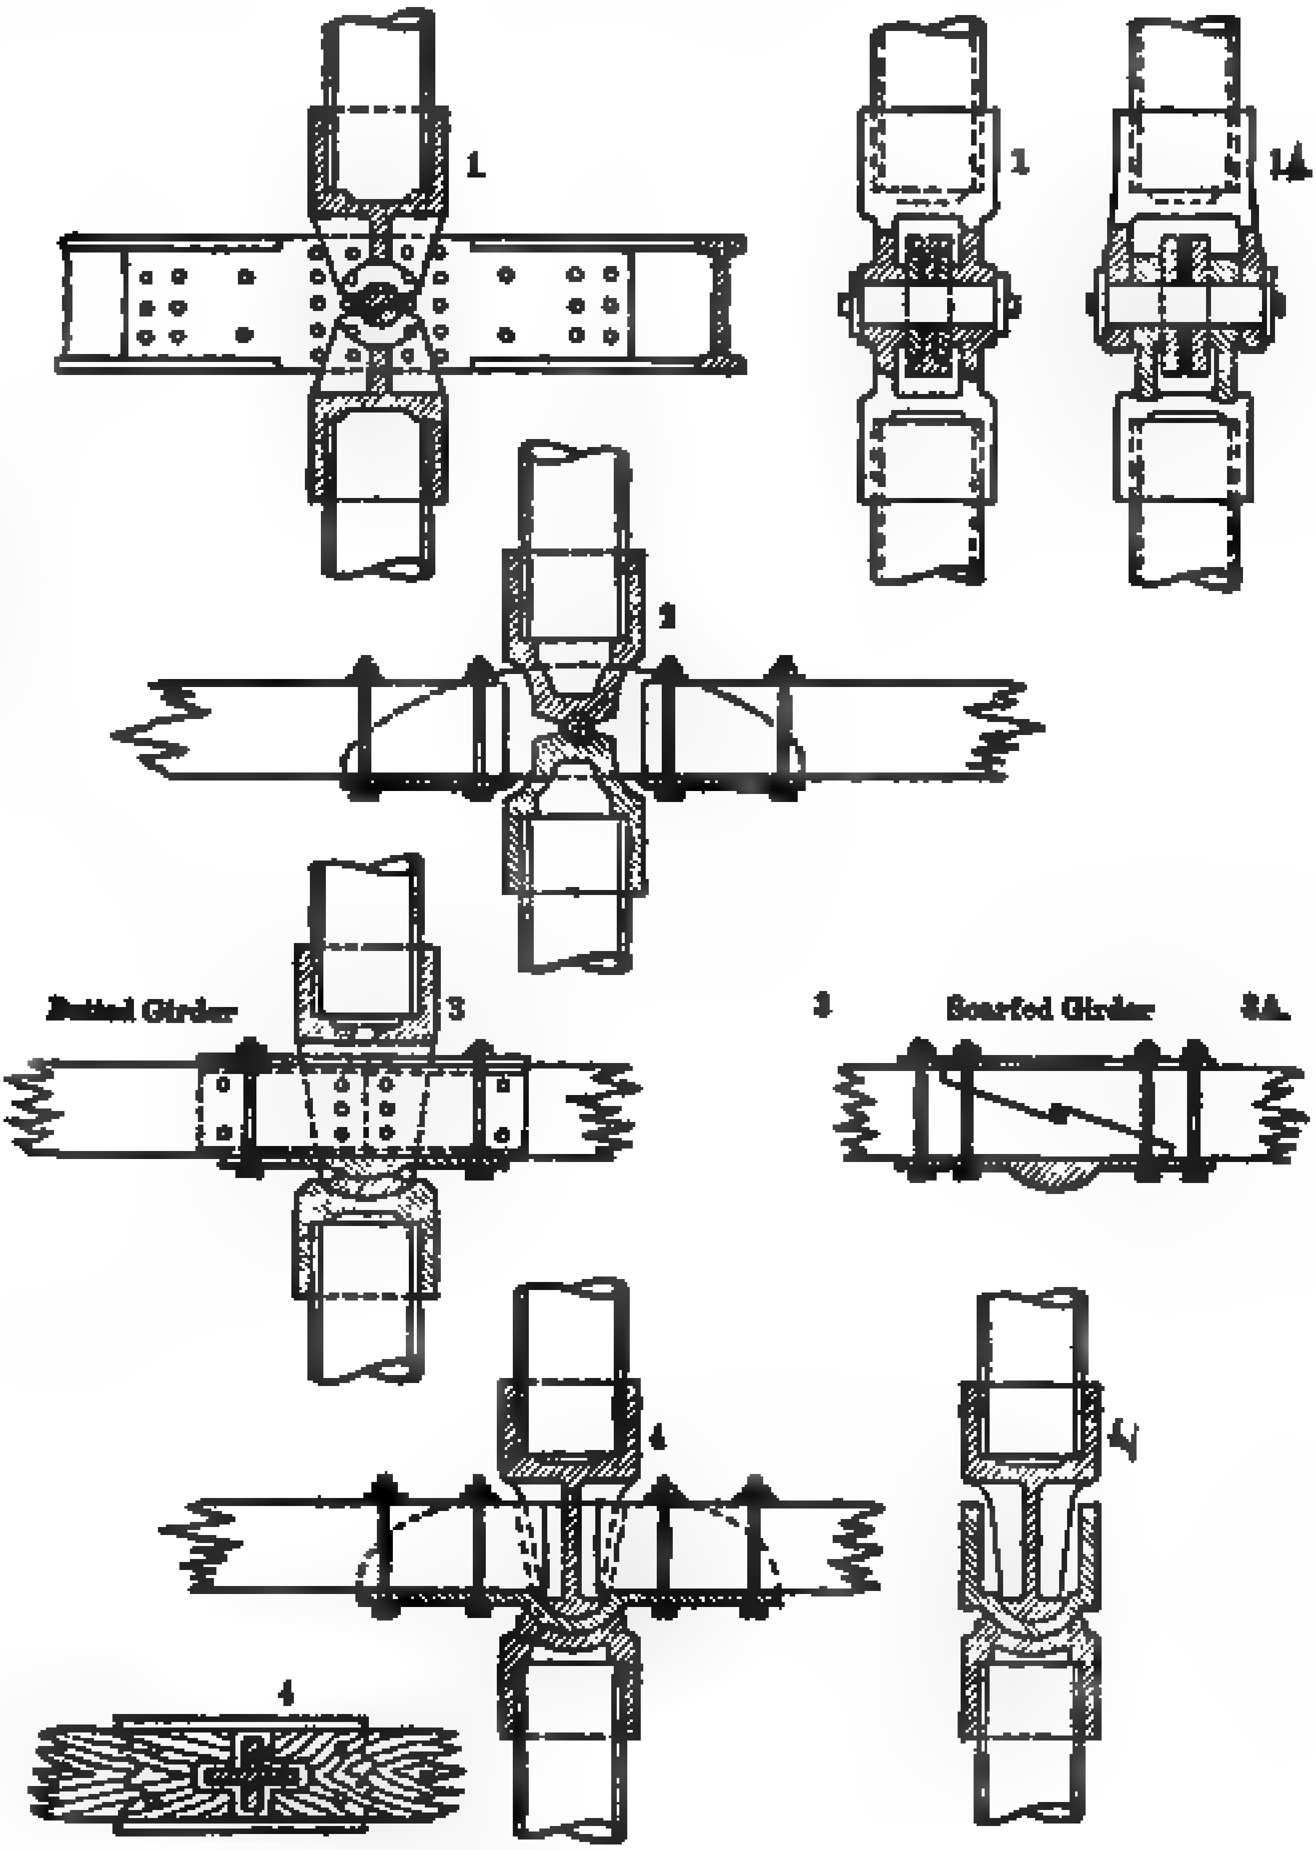

Fig. 11. Connections, Caps and Bases for Steel-pipe Columns

...ns to carry wooden girders is shown in Figs. 62 and 63 of Chapter XXII. ...e are many other forms of cast and wrought caps for pipe-columns. The ...n of proper caps and bases is the most difficult part of adapting tubular ...s to practical problems in building-construction. Figs. 10 and 11 show

various forms of steel-pipe column-connections, caps and bases sufficiently s
gestive to enable a designer to properly develop their details.

Advantages of Steel-Pipe Columns. A wrought-steel pipe when u
as a column generally has the following advantages:

(1) It will support a greater load per square inch of cross-section than
other shapes and styles of mild-steel columns of the same SLENDERNESS-RA
l/r, for most of the columns of different slenderness-ratios recently tested (1
and 1909) at the Watertown Arsenal.

(2) Its section has the greatest possible LEAST RADIUS OF GYRATION, r,
the same outside diameter and section-area. This makes pipe-columns es
cially advisable when it is desired to obstruct the view as little as possible, a
the corners of show-windows, in balcony-supports, etc.

(3) It may be used with greater slenderness-ratio, l/r, than any other sec
without reducing the load per square inch in order to conform to permiss
loading-rules, such as those of the New York City and the Chicago buil
codes.

(4) Its curved walls permit the use of relatively thinner material than
be used with columns with flat surfaces; that is, its thickness, t, divided by
outside diameter, d, may be $t/d = 1/80$ with as great security from WRINKL
called also BUCKLING, BULGING OR LOCAL FAILURE, as the box column, w
good practice of competent engineers limits to 1/40 of the unsupported wi
of flat surfaces. The ratio $t/d = 1/80 = 1/4''/20''$ is about the limit of practic
working of the ordinary lap-weld process, and all commercial pipes have a sma
ratio.

(5) Manufacturers are now regularly making pipes for sizes up to and inc
ing 16 in outside diameter, in lengths up to 40 ft.

Notes on the Use of Steel-Pipe Columns. The following general n
and suggestions should be observed in the use of steel pipe for columns:

(1) As in the case of columns of any construction, it is obvious that c
petent designing and detailing as well as proper fabrication of the END-CON
TIONS for pipe-columns be insisted upon. Otherwise the advantages of
circular section may be nullified.

(2) When the loading must be ECCENTRIC care must be exercised in the pr
selection and size of pipe to be used. The relative economy in the use of
circular section, however, increases with the length and slenderness of the colu

(3) A CAPITAL OR BASE should never be screwed to a pipe, because cut
the thread reduces the section. Where screw-threads must be used, only
area below the root of the threads should be considered as available for the
porting power.

(4) The ends of a pipe to be used for a column should always be FACED
in a lathe, the facing being normal to the general axis. A pipe should no
turned nor bored in fitting capitals or bases but, if possible, the capital or
should always be FORCED OR SHRUNK to an even bearing on the faced end o
pipe. Where the capital or base must be inserted, it is liable to start a wri
or buckle and the load should be adjusted to the probable lessening of suppo
power. The bearing surfaces in capitals and bases should be, of course, al
LATHE-FACED. It may be found that with careful foundry-work it is not n
sary to bore the castings; but it may, in some cases, be cheaper to use relati
poor foundry-work and bore the castings, as well as face the seats.

(5) PIN-ENDS OR BALL-AND-SOCKET ENDS are generally preferable to
or fixed ends for a slenderness-ratio l/r, of 100 or less, because tests show
columns so fitted usually carry heavier loads before failure. This is increas

...at as l/r decreases. Any form of end-connection of column that may ...a flexure from a falling floor may endanger the whole structure.

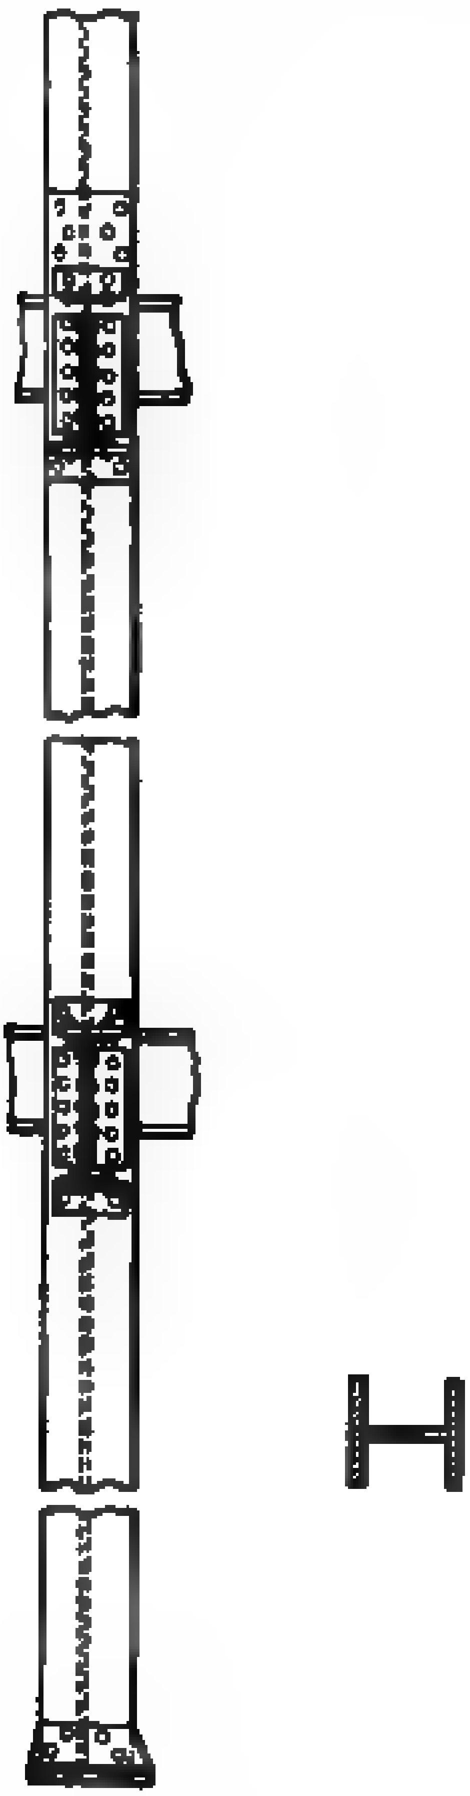

Fig. 12. Connections for Bethlehem H Columns

...) "All columns should have sufficient STIFFNESS to safely withstand the ...er deflecting forces to which they may be exposed. This usually involves ...iderations of eccentricity as well as of flexure due to transverse load.

...) "It is desirable to adhere always to the trade sizes of pipe known as ...EAST, STANDARD, EXTRA STRONG, DOUBLE-EXTRA STRONG, CASING, BOILER-

TUBES, etc., and avoid special production which usually entails delays and spec prices.

(8) Tables XII and XIII give the safe loads which STANDARD and EXTR STRONG steel-pipe columns are permitted to carry under the New York a Chicago codes. Philadelphia laws permit slightly grea loads. Supplementary tables of safe loads for DOUB EXTRA STRONG steel-pipe columns are furnished by t manufacturer and may be useful in cases where a mi mum diameter is required; but it should be remembe that such pipe always costs more per pound, owing to greater cost of manufacture.

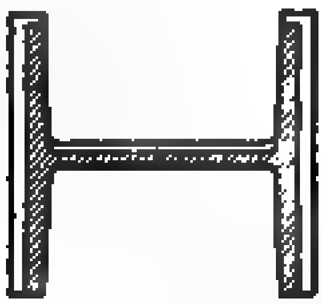

Fig. 13. Section of Bethlehem H Column Showing Variation in Area

H-Beam and I-Beam Struts and Columns. F struts and columns carrying light loads, H BEAMS a I BEAMS are probably the most economical, as the require very little riveting except for the splices an connections. Owing, however, to the narrow flanges o even the deepest I beams it is not practicable to rivet very heavy girders to them nor can they ordinarily be riveted to the web, because the latter is generally s

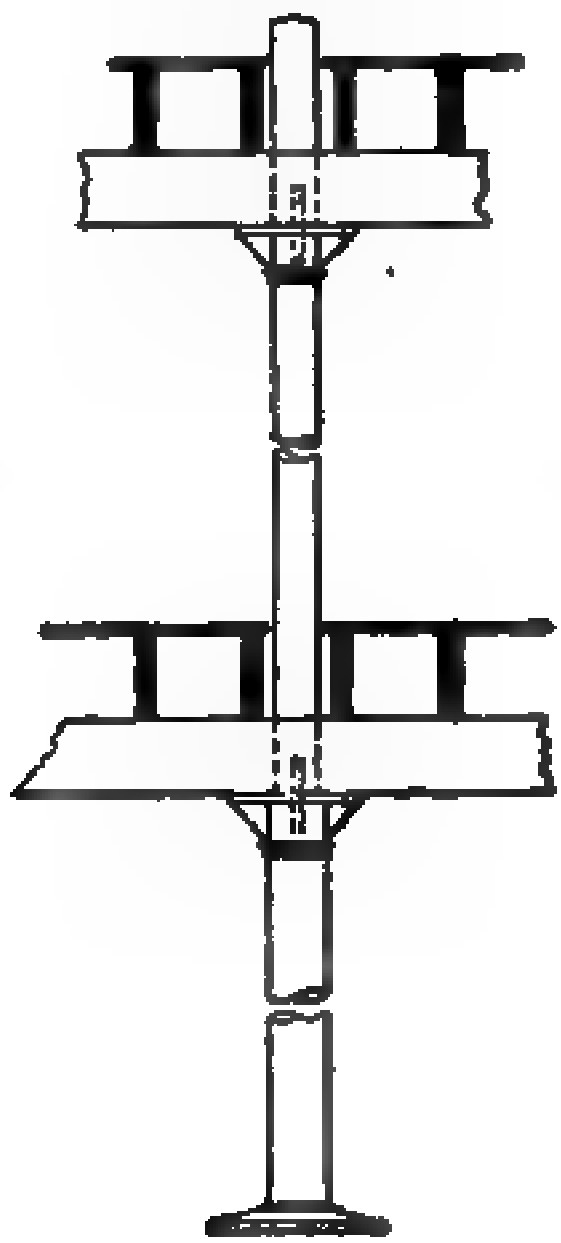

Fig. 14. Concrete-filled Lally Steel Column

Fig. 15. Lally Column. Typic Connections

thin that too many rivets will be required for the connection. Tables XVII a table of safe loads for the Carnegie steel H BEAMS or I BEAMS used columns.

Bethlehem Columns. As far as shop-work is concerned the Bethlehem columns are just as economical as the ordinary H-beam or I-beam columns as they, also, are rolled and not built up or assembled. The only fabrication required is that for the splice-plates and connections. Typical connections are shown in Fig. 12 from which the simplicity of detail and small amount of fabrication required are apparent. They are, moreover, superior to the I-beam columns because they afford a wider flange for attaching the beams and girders, besides being

more economical of cross-section. Bethlehem columns are rolled in five size 6, 8, 10, 12, and 14 in in width, but by spreading the rolls, as shown i Fig. 13, the section-area of each width can be increased considerably. Th

1902, it was not until the establishment in 1908 of the larger improved mills at Bethlehem, Pa., that these sections became available for use in this country. They are gradually superseding plate-and-angle and box columns, particularly those of the smaller sizes. The 6-in columns have been rolled since 1920.

Lally Columns. LALLY COLUMNS (see, also, pages 469 to 474 and Tables on page 516) are patented columns made with a circular steel shell, as shown in Fig. 14, and filled with a concrete composed of sand, cement and blue trap-rock, and thoroughly compressed. The larger columns have, in addition, a steel reinforcement, which makes a light, but strong support. They are in many buildings replacing masonry piers for supporting girders because of the saving in space, and are extensively used in mill-construction. Typical connections are shown in Fig. 15. The Lally formula for the safe loads in tons is given with Tables XXII and XXIII, page 516.

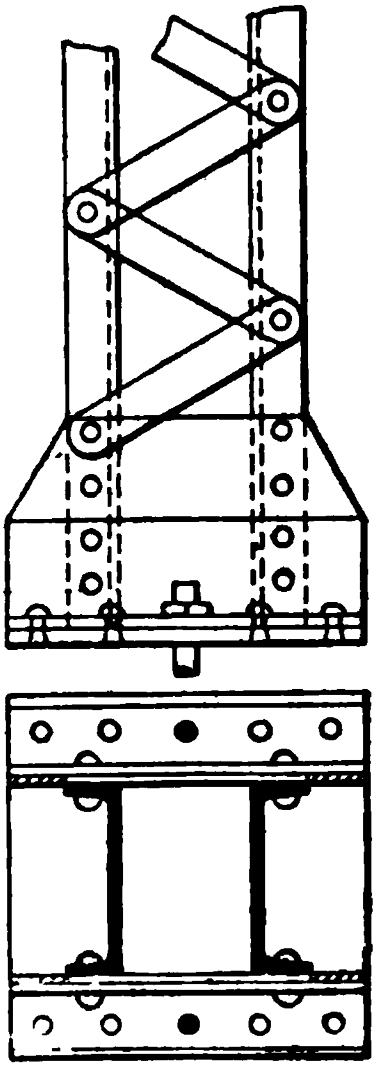

Fig. 19. Steel Channel-column with Lattice-bars

Plate-and-Angle Columns. Four angles and a plate riveted together as shown in Fig. 16 are now being extensively used in building-construction; particularly for columns having an unsupported length of less than 90 radii; also for the outer columns in steel-mill buildings, and for light columns supporting the roofs of railway stations, etc. Columns with this form of cross-section are especially convenient for making beam and girder-connections and for splicing, and are also well adapted to resist eccentric loads. The width of the plate is generally such that the LEAST RADIUS OF GYRATION is in the direction r_2, and this radius may be obtained directly from Tables XVI and XVII, pages 370 and 372.

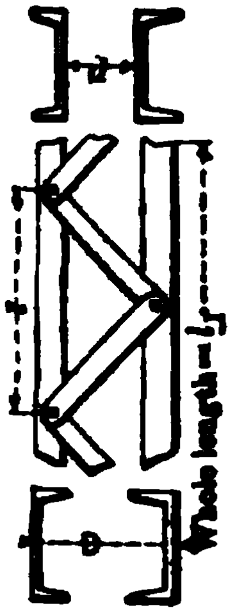

Fig. 20. Spacing of Lattice-bars in Channel-columns

Channel-Columns. Typical COLUMN-DETAILS for plate-and-angle and channel-columns, taken from the Carnegie Pocket Companion, 1915 edition, are shown in Figs. 17 and 18 and represent recent practice in office-building construction.

Lattice-Columns. Two channels, set back to back, at such a distance that the radii of gyration will be equal about both axes, and connected by lattice-bars, as shown in Fig. 19, make a very desirable column for moderate loads, as in the upper stories, or in buildings of three or four stories in height. For greater loads, short cover-plates may be riveted to the flanges in place of the lattice-bars. Such columns are very satisfactory, especially for making connections.

Rule for Latticing of Channels and Angles. When channels are connected by lattice-work, as in Fig. 20, in order that there may not be a tendency

in the channels to bend between the points of bracing, the distance l should be made equal to the total length of the strut multiplied by the least radius of gyration of a single channel, and the product divided by the least radius of gyration for the whole section; or,

$$l = rl_1/r_1$$

in which l = length between points of bracing;
l_1 = total length of strut;
r = least radius of gyration for a single channel;
r_1 = least radius of gyration for the whole section.

This same rule will also apply to angles, although with them the lattice-work is generally doubled, as in Fig. 21.

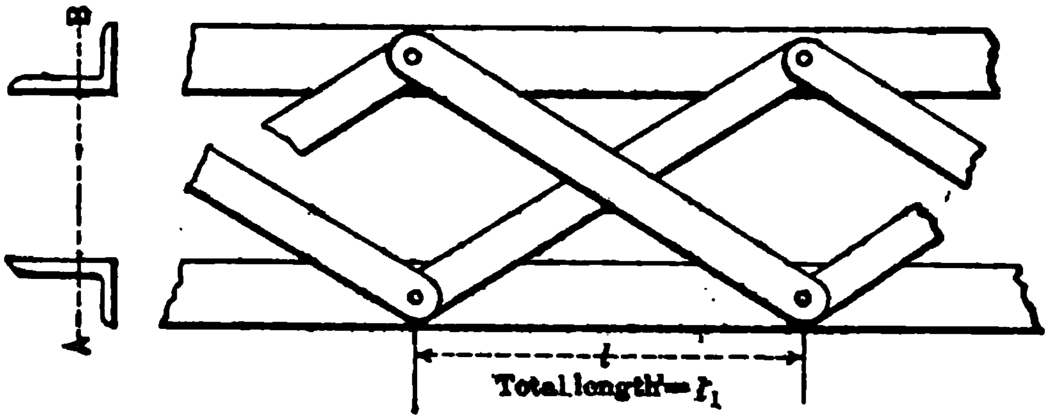

Fig. 21. Double Lattice-bars on Angle-columns

It is generally found desirable to make the distance l less than that obtained by the above formula. The inclination of the lattice-bars with the axis of the column or strut is usually about 60° for single and 45° for double bars.

The proper distance for d or D, Fig. 20, for a pair of channels, so that the radii of gyration will be the same in both directions, is given in Table VII, page 359.

The following tabulations are taken from the Handbook of the Cambria Steel Company, 1915 edition.

Sizes of Lattice-Bars to be Used with Latticed Channel-Columns

Depth of channels	Dimensions of lattice-bars		Weight of lattice-bars per foot	Center of hole to end of bar, a	Distance center to center of rivets, d		
	w	Thickness			Maximum		Minimum
in	in	in	lb	in	ft	in	in
6	1½	¼	1.28	1⅛	0	11½	6⅝
7	1¾	¼	1.49	1⅛	1	1½	7⅝
8	2	5/16	2.12	1¼	1	3	8 11/16
9	2	5/16	2.12	1¼	1	4½	9½
10	2	⅜	2.55	1¼	1	6½	10 11/16
12	2¼	⅜	2.87	1⅜	1	10½	13
15	2½	⅜	3.19	1½	2	2½	15 5/16

Sizes of Stay-Plates to be Used with Latticed Channel-Columns

Minimum size of stay-plates at ends of columns			Weight of minimum stay-plates	Diameter of rivets	
b	Thickness	*l*			
in	in	in	lb	in	
8¼	¼	7½	4.38	⅝	9¼	¼	10	6.55	⅝	
10½	5/16	9	8.37	¾	
11¼	5/16	12	11 95	¾	
12¼	⅜	12	15 62	¾	
14¼	⅜	15	22 73	¾	
16¼	⅜	15	25.90	¾	

Plate-and-Angle and Box Columns. Plate-and-angle columns, as shown in Fig. 16, requiring but two rows of rivets are very economical columns for buildings of moderate height, as they afford excellent opportunities for connecting the beams and girders. Tables of SAFE LOADS are given in Table XXIV of this chapter. When a more compact section is required than that afforded by the larger sizes, the section-area may be increased by riveting plates to the angles as shown in Fig. 22 which is a section of one of the columns in the Munic-

Fig. 23. Heavy Plate-and-angle Two-web Column

Fig. 24. Heavy Plate-and-angle Three-web Column

York City. This, however, greatly increases the expense nd it is therefore usually more economical to substitute s, or channel or box columns. For high buildings or heavy uired sectional areas of columns are greater than can be annel-columns or Bethlehem columns without flange-plates, f plates and angles, as shown in Fig. 23, which is one of the ers' Trust Company Building, New York City, will prob- more satisfactory. The thickness and number of web-plates be varied with the load to be supported. Ordinary con- umns are the same as those for CHANNEL-COLUMNS, shown tallest buildings and heaviest loads box columns with n in Fig. 24 are the best. They are used in the highest h as the Masonic Temple in Chicago, and the Bankers'

Trust Building, the Municipal Building, the Woolworth Building and the M
ropolitan Tower in New York City. Fig. 24 is a cross-section of one of
columns in the last-mentioned building. Details of a similar column use
the Bankers' Trust Company Building are shown in Fig. 7 on page 342.
is of course impracticable to give tables of SAFE LOADS for PLATE-AND-AN
COLUMNS with flange-plates and for BOX COLUMNS, owing to the great variet
combinations that can be used, but Example 10 of this chapter shows how
columns are designed and their strength determined. (See page 485.)

Steel Struts in Trusses. These are generally made of a pair of latt
channels, or of channels and plates for heavy trusses with pin-connections,
of either a pair of light channels or a pair of angles with uneven legs for l
trusses. For roof-trusses having a span not exceeding 80 ft, a pair of 4 by
3/8-in angles is generally sufficient for any of the compression-members un
they are subjected to TRANSVERSE STRESS; and the minor struts are very o
made of a pair of 3 1/2 by 2 1/2 by 1/4-in angles. The angles are placed from
3/8 in apart to permit the filler-plates used at the joints to go between th
For compression-members subject to transverse stress a pair of channels
erally offers the best section. If necessary the channels can be reinforced
plates at the top and bottom. A pair of angles, with a deep web-plate riv
between, is often used for the principles of Fink trusses where they are sub
to a slight transverse stress. (See, also, Fig. 6, page 1146.) For very l
compressive stresses and for short members a single angle is sometimes used;
this is not considered good practice, as it causes eccentric loading on the gu
plates at the truss-joints. A pair of small angles, or some other combina
with a symmetrical cross-section should always be used for truss-members
. Where angles are used in pairs they should be connected by a rivet and s
filler-plate or separator every two feet in length, to prevent them from sp
ing apart. In regard to the maximum length of steel struts in trusses
not considered good practice to use a strut whose unsupported length exc
150 times its least radius of gyration, or 50 times its least width.

13. Strength of Steel Columns. Formulas

Principles Governing the Resistance of Built-up Steel Columns.
fessor William H. Burr states * that "the general principles which gove
resistance of built-up columns may be summed up as follows: the ma
should be disposed as far as possible from the neutral axis of the cross-se
thereby increasing the radius of gyration, *r*; there should be no initial in
stress; the individual portions of the column should be so firmly secured t
other that no relative motion can take place, in order that the column m
as a whole, thus maintaining the original value of *r*." The experiments
by Professor Burr indicate that a closed column is stronger than an ope
It should also be remembered that any column such as an I beam, chan
angle, the cross-section of which has a maximum and a minimum rad
gyration, is not economical for use under a single concentric load, as the
mum radius of gyration must be used in the calculation, and part of the
rial is to a certain extent wasted when the ideal efficiency of the col
considered.

Formulas for Steel Columns. A great many FORMULAS are used
culating the strength of steel columns and struts, of the lengths usua
ployed in practice, but scarcely any two authorities agree upon the sa
These formulas may all be grouped into two general classes, those

* Elasticity and Resistance of the Materials of Engineering, by William H.

RANKINE'S FORMULA * (11) and those founded on the STRAIGHT-LINE FORMULA). (See the following paragraphs.) In the different formulas different values assigned to the ARBITRARY CONSTANTS. Previous to 1888 RANKINE'S or ...DON'S FORMULAS were almost universally used for all columns, although with ...or less variation in the constants employed. About 1885 Professor Burr, ...r having conducted a series of tests upon full-size column-sections deduced ...t is now known as the STRAIGHT-LINE FORMULA. As this is easier of applica...n than RANKINE'S FORMULA, it has gradually found favor with engineers, espe...lly as the results differ but little from those obtained by the older formula.

...mulas Compared. Which one, of all the formulas in use, should be ...ployed in calculating the safe load for columns is an open question, but the ...thor, after careful deliberation, has decided to recommend RANKINE'S FOR...MULA for the following reasons. In the first place it is safe and conservative ...d if it errs at all, it is on the side of safety; and in the second place it has a ...der application, as the values assigned to the arbitrary constants have been ...re generally agreed upon, whereas there is a greater variety in the values of ...e constants employed in the STRAIGHT-LINE FORMULA. Of course one is not ...e to choose when city laws compel the use of certain formulas. No tables of ...E LOADS for columns, satisfying the requirements of all cities, could be com...d. The author has accordingly thought it best to insert the various tables ...SAFE LOADS for different forms of columns as computed in the very latest ...dbooks although not necessarily based upon RANKINE'S FORMULA, and to ...t Table XI, specially computed and giving the comparative SAFE LOADS IN ...S PER SQUARE INCH OF METAL-AREA for columns, as determined by seven ...ferent formulas. (See pages 493 to 495.)

...mulas Used in Building Codes. RANKINE'S FORMULA (called GORDON'S ...ULA in many codes) is specified in the building codes of the following cities: ...adelphia, Pittsburgh, Baltimore, and Milwaukee; and in the Cambria ...book. The STRAIGHT-LINE FORMULA is specified in the building codes of ...w York City, Chicago, St. Louis, Minneapolis, Boston, and in many other ...s, and is used in the Carnegie and Bethlehem handbooks.

...mulas Used in Practice. The following formulas, in the opinion of the ...or, represent the best current practice. They are FORMULAS FOR SAFE ...s, S, in pounds per square inch of cross-section, on steel columns and struts. ...se formulas l is the LENGTH of the column in inches and r the LEAST RADIUS ...RATION of the cross-section. (See, also, Chapter X, pages 333, 344, etc.) ...e SAFE LOAD, P, for any column is equal to S, obtained by one of the follow...formulas, multiplied by the SECTION-AREA of the column in square inches;

$$P = AS \qquad (10)$$

...ine's formula, used in the Cambria handbook, is

$$S = \frac{12\,500}{1 + l^2/36\,000\,r^2} \qquad (11)$$

...formula recommended by Professor Burr is

$$S = 10\,000 - 40\,l/r \qquad (12)$$

...formula used by the American Bridge Company and Carnegie's Pocket ...panion is

$$S = 19\,000 - 100\,l/r \qquad (13)$$

...maximum of 13 000 lb per sq in.

* ...kine's formula is sometimes referred to as Gordon's formula, but Gordon used ...t lateral dimension or the diameter of the column instead of the least radius of ...of the cross-section.

The formula used by the American Railway Engineering Association the New York and Chicago building codes is

$$S = 16\,000 - 70l/r$$

with a maximum of 16 000 lb per sq in for New York and 14 000 for the ot

The formula used in the New York City building code previous to 1916

$$S = 15\,200 - 58\,l/r$$

The formulas used in the Catalogue of the Bethlehem Steel Company are

$$S = 16\,000 - 55\,l/r, \text{ for } l/r \text{ over } 55$$

and $S = 13\,000$ lb per sq in, for l/r under 55

Fowler's slightly modified formula for steel struts in trusses is

$$S = 12\,500 - 50\,l/r$$

The value 50 in Fowler's formula is 41⅔ when l is in inches, and 500 w is in feet.

For a comparison of most of these formulas, see Table XI, pages 493 to and the COMPARATIVE DIAGRAM OF FORMULAS, page 496.

14. Design of Steel Columns. Examples

Practical Use of Column-Formulas. Unlike the beam-formula the co formulas in general use do not give a direct method of calculating the dime of a column that will support a given load, owing to the presence in the co formula of two unknown quantities, A and r, which are dependent upo another. Hence in designing columns, the section must be first assume then tested for the safe load P, or for the maximum unit fiber-stress S. T an apparently roundabout method of designing columns, but unfortu there seems to be no more direct way. When a column is to be select designed, its axial load P is given and also its length and the condition ends. A proper allowable unit stress, S, is assumed, suitable for the material and for the conditions under which it is to be used, or in acco with the requirements of the local building code; or the value of S is gi the specification according to which the column is to be designed. A section is then selected in accordance with the principles explained on pag to 469. For this assumed cross-section A and r are determined and the stituted in the formula, which is solved for P. If the assumed dimensio a value for P that agrees with the actual load, they are correct. If, ho the resulting value of P is smaller than the actual load, the assumed size small, and it will be necessary to choose a larger size and solve again. the contrary, the actual load is less than the safe calculated load, a colum a smaller element of cross-section is assumed and a new value of P ob After a few trials a size that gives a satisfactory result for the required con will be found.

Examples Illustrating the Use of Column-Formulas and Tables. the column-tables in the last half of this chapter give the safe loads of the ity of column-sections of current practice, having determined which sec is most advisable to use under any given conditions, it is merely neces consult the tables and select the column of the required size to support the load.

Example 7. The following is an example showing the method of s BETHLEHEM ROLLED H COLUMNS for buildings.

Example Showing the Method of Selecting Bethlehem Rolled H Columns for Buildings

For illustration, the interior columns of an actual sixteen-story building are taken as example. The story-heights and the loads on the columns are given in the following tabulation:

Stories	Heights of stories, ft	Loads on columns, tons	Safe loads, tons	H column-section required: Dimensions: D, in	T, in	B, in	Weights of sections, lb per lin ft	Section-numbers
16th	12	27	55.0	7⅛	7/16	8.00	31.5	H8
15th	13	53	81.5	8⅜	11/16	8.12	48.0	H8
14th	14	79						
13th	13	104	132.2	10⅜	13/16	10.12	71.0	H10
12th	13	128						
11th	13	151	174.8	12¼	⅞	12.08	91.5	H12
10th	13	174						
9th	13	197	219.1	14¼	15/16	14.08	114.5	H14
8th	13	219						
7th	13	241	263.8	14⅝	1⅛	14.19	138.0	H14
6th	13	261						
5th	13	281	310.1	15	1 5/16	14.31	162.0	H14
4th	13	301						
3d	13	321	341.3	15¼	1 7/16	14.39	178.5	H14
2d	15	341						
1st	17	363	403.5	15¾	1 11/16	14.54	211.0	H14
Basement	12	395						

D is the depth of the column, *T* the thickness of the flanges and *B* the breadth of the flanges.

Columns for buildings are usually selected in lengths of two stories. By inspection of the tables of safe loads for H columns, it is found that no columns smaller than 14-in H sections have sufficient capacity for the lower stories. Where there is no limitation as to the size of the column, the column with the largest dimensions and having the required capacity will be the most economical. The unsupported length of a column should not exceed 150 radii of gyration, which is the limit of length for which safe loads are given in the tables. In the best practice the unsupported length of a column is frequently required not to exceed 120 or 125 times the least radius of gyration; various limits for l/r are indicated in the tables by zigzag lines. The safe loads given in the tables are for concentric or symmetric loading. When the loads are not centrally or symmetrically applied, the size of the column should be calculated by Formula (18), page 486.

Example 8. Suppose that in a 20-story office-building to be erected in Chicago, the load on each of the first-story columns, which are 16 feet in length, is 700 tons. What columns should be used?

Turning to Table XXI, page 515, giving ~~the safe loads for~~ Bethlehem 14-in columns it is seen that a 14-in 287.5-lb column, the heaviest rolled, will support only 549.3 tons; this type of column, therefore, cannot be used. More-

over a casual inspection of the tables of safe loads for plate-and-angle channel-columns shows that they are not suitable because of the thick flan and web-plates required. Consequently the columns in the lower stories probably have to be of the box type, with double or triple webs, as shown Figs. 23 and 24. The upper columns, however, may be of the plate-and-an or channel-type, whichever will be the more economical. The heaviest pl and-angle column, without flange-plates (Table XXIV, page 522), composed four 6 by 4 by ¾-in angles and one 12 by ½-in web, will support, for a len of 14 feet, the height of most of the upper stories, 469 000 lb; and a channel-umn (Table XXVI, page 541) composed of two 12-in 30-lb channels and 14 by ¾-in plates will support 502 000 lb. The former weighs 125 and the la 131.4 lb per lin ft, so there is not much choice as far as economy of materia concerned. The channel-column, however, requires four rows of rivets w the plate-and-angle column requires only two rows, so this added expens fabrication would have to be considered. Assuming, however, that the pl and-angle type is more desirable, the next step is to design the individ columns.

The load upon each of the uppermost columns, which are 20 ft in length 70 000 lb. Turning to Table XXIV, page 518, it will be seen that a colu composed of four 4 by 3 by ⅜-in angles and one 8 by ⅜-in web will supp for a length of 20 ft, 77 000 lb; but this load is below the lower zigzag line hence the slenderness-ratio of the column exceeds 120. Assuming, for the p pose of illustration, that the limit of l/r is 120, a heavier section must selected. On page 519 of Table XXIV, continued, it is seen that the ligh 20-ft column, for which l/r does not exceed the required ratio, is one compo of four 5 by 3½ by ⅜-in angles and one 10 by ⅜-in web, and that for a len of 20 ft it will support 121 000 lb, or 51 000 lb more than will come upon it.

Continuing the design of the columns, suppose that one in the 14th st 14 ft in length, supports 175 tons, or 350 000 lb. From Table XXIV, page it is found that a column composed of four 6 by 4 by ⅝-in angles and one 12 ½-in web-plate, for a length of 14 ft, will carry 373 000 lb. In the table, safe load is calculated by Formula (13), whereas the Chicago Building C specifies Formula (14). Hence, as this building is to be erected in Chicago, chosen column must be tested by the latter formula. Its A is 29.44 sq in its least r, 2.65 in. To test it by the formula, $l = 14$ ft $\times 12 = 168$ in, and $l/$ 168 in/2.65 in $= 63$. Substituting in Formula (14), $S = 16\,000 - (70 \times 63$ $16\,000 - 4\,410 = 11\,590$ lb per sq in. From Formula (10), the safe load for column, $P = AS = 29.44$ sq in $\times$ 11 590 lb per sq in $=$ 341 209 lb, which is than the actual load. Therefore, the next heavier column, with angles 1½ thick, should be selected.

Example 9. In an office-building to be erected in Philadelphia, the use of Bethlehem rolled-steel H columns has been decided upon. One of these umns, 15 ft in length, supports 170 000 lb, or 85 tons. What should be the of this column?

According to Table XIX, page 508, giving the safe loads for Bethlehem umns, a 10-in 49-lb column, 15 ft in length, will carry 86.3 tons, an appare safe load. Bethlehem-column loads, however, are calculated by the straight-formula, whereas in Philadelphia, Rankine's (called Gordon's) formula is standard. This formula with the arbitrary constants inserted is

$$S = \frac{16\,250}{1 + \frac{1}{11\,000}(l/r)^2}. \quad \text{(See Table XI, page 493.)}$$

from Table XIX, $A = 14.37$ sq in and the least $r = 2.49$ in; l is 15 ft or 180 in
$l/r = 180 \text{ in}/2.49 \text{ in} = 72.3$.

Substituting in the formula,

$$S = \frac{16\,250}{1 + \frac{1}{11\,000}(72.3)^2} = \frac{16\,250}{1 + 5\,227/11\,000} = \frac{16\,250}{16\,227/11\,000}$$

$$= \frac{16\,250 \times 11\,000}{16\,227} = \frac{178\,750\,000}{16\,227} = 11\,015 \text{ lb per sq in}$$

and from Formula (10), page 481,

$$P = AS = 14.37 \text{ sq in} \times 11\,015 \text{ lb per sq in} = 158\,285 \text{ lb or } 79.1 \text{ tons},$$

which is less than the tabular load. Hence the next heavier column, weighing 54 lb per sq ft, would have to be used.

Example 10. Figure 7, page 342, shows the cross-section of one of the basement-columns in the Bankers' Trust Company's Building, New York City. It is 20 ft in length and supports 2 230 tons. Is the column safe?

The first step is to find its least radius of gyration which is equal to $\sqrt{I/A}$. The least moment of inertia of this section was found to be 17 030. (See page 343.) The area is made up as follows:

FLANGES. The flanges are composed of six 27 by ¾-in plates and two 27 by 1 1/16-in plates. The area of the cross-section of each 27 by ¾-in plate is 20.25 sq in and of the six plates, 121.50 sq in. The area of the section of each 27 by 1 1/16-in plate is 18.56 sq in and of the two plates, 37.12 sq in. Hence the total sectional flange-area is 121.50 + 37.12 =	158.62 sq in
FLANGE-ANGLES. Each flange-angle is 6 by 6 by 15/16 in. Its section-area is 10.38 sq in. Hence for the four, $A = 10.38 \times 4 =$	41.52 sq in
OUTER WEB. The outer web-plates are each 18 by 1 1/16 in. The area of each one is 12.375 sq in and of the eight	99.00 sq in
WEB. Each web-angle is 6 by 3½ by 15/16 in with a section-area of 8.03 sq in; and for four angles the section-area is	32.12 sq in
WEB. The web is composed of two 18 by 9/16-in plates, each with a section-area of 10.125 sq in. For two the area is	20.25 sq in
The area of the entire section, therefore, is	351.51 sq in

$$r^2 = I/A = 17\,030/351.5 = 48.5 \quad \text{and} \quad r = \sqrt{48.5} = 7 \text{ in}$$

$$l = 20 \text{ ft} = 240 \text{ in and } l/r = 240 \text{ in}/7 \text{ in} = 34.3$$

Substituting in the former New York City building code Formula (15), page 482,

$$S = 15\,200 - 58 \times 34.3 = 15\,200 - 1\,989 = 13\,211 \text{ lb per sq in}$$

From Formula (10)

$$P = AS = 351.5 \text{ sq in} \times 13\,211 \text{ lb per sq in} = 4\,643\,666 \text{ lb, or } 2\,321 \text{ tons.}$$

Hence the column is perfectly safe.

15. Eccentric Loading of Steel Columns

General Principles. Where columns are used in tiers, one above another, the beams and girders which they support must necessarily rest upon brackets projecting or extending varying distances beyond the shell or section-areas or of the columns. Such connections cause BENDING MOMENTS in the columns. When equal loads are applied at equal distances on opposite sides of a column,

the bending moments caused by them in the column balance each other, an the CENTER OF STRESS may be considered as coinciding with the axis of th column. When, however, a load is applied on one side (Fig. 25) without corresponding load on the opposite side, it is called an ECCENTRIC LOAD and th area of the cross-section of the column should be increased correspondingl There is unfortunately no direct method by which this additional area can l determined. The usual method of procedure is to assume a section in exce of that required to support the total load and then compute the fiber-stress d to the combined balanced and eccentric loads. If this works out too lar or too small another trial is made.

Formula for Eccentric Loads on Steel Columns. The following form (compare with Fig. 25) is used to determi the combined fiber-stresses due to the conce tric and eccentric loads (See, also, page 453):

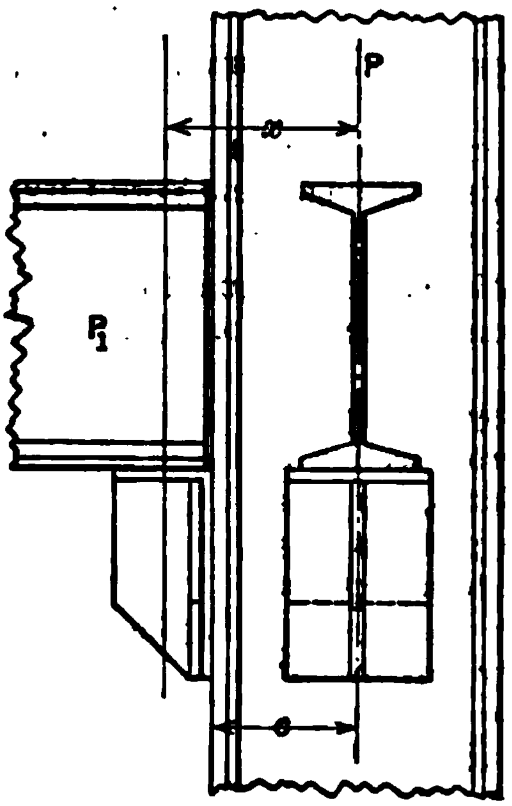

Fig. 25. Channel-column with Eccentric Load. Elevation

Let P = the concentric or balanced load pounds,
P_1 = the eccentric load in pounds,
M = the bending moment due to t eccentric load in inch-pounds = P
x = the eccentricity of the load P_1 inches. (See note below:)
I = the moment of inertia of the ar of the cross-section of the colu about an axis at right-angles to t direction of the bending,
c = the distance of the outermost fiber the cross-section from the same a
A = the area of column-section in squ inches and
S = the actual fiber-stress in pounds p square inch

Then

$$S = (P + P_1)/A + Mc/I \qquad ($$

Note. In measuring the ECCENTRICITY, the distance, x, is generally measu from the axis of the column to the center line or half-breadth line of the brac or bearing.

Examples of Eccentric Loading of Steel Columns. The following e amples illustrate the use of the formula and tables in determining the safe eccentric loads for steel columns.

Example 11. The total load on the top of a column 32 ft in length is 194 000 lb, of which 30 000 lb come from the end of a girder. There is no corresponding load on the opposite side. (See Fig. 26.) It is proposed to use a channel-column. What is the size of the required column?

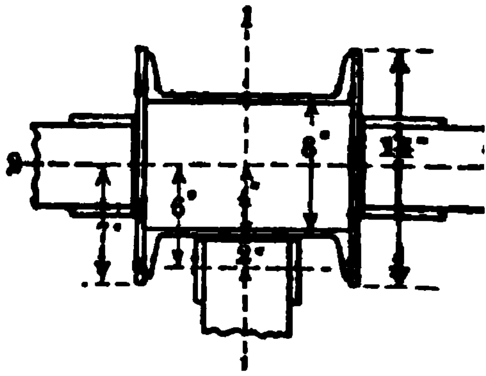

Fig. 26. Channel-column w Eccentric Load. Section

By referring to Table XXVI, page 539, it is seen that a column composed of two 12-in 20.7-lb channels and two 14 by ⅜-in plates will support, for a length of ft, 227 000 lb, a somewhat greater load than will come on the column. I the section of this column, I_{2-2} = 415, A = 22.56 sq in, r = 4.29 in and $L/$

$84/4.29 = 89$. Substituting in Formula (11), page 481, to find the safe unit fiber-stress

$$S = \frac{12\,500}{1 + \frac{1}{36\,000}(l/r)^2} = \frac{12\,500}{1+(89)^2/36\,000} = \frac{12\,500}{1+7\,921/36\,000} = \frac{12\,500}{43\,921/36\,000}$$

$$= \frac{12\,500 \times 36\,000}{43\,921} = \frac{450\,000\,000}{43\,921} = 10\,245 \text{ lb per sq in}$$

The actual stress in pounds per square inch of the column-section is found by Formula (18), $S = (P + P_1)/A + Mc/I$. $P = 164\,000$ lb, $P_1 = 30\,000$ lb, $A = 22.56$ sq in and $M = P_1x$ in-lb. $x =$ the distance in inches from the axis 2-2 of the column to the outside of the web, plus the distance from the outside of the web to the center of the bracket. The former distance can be found from Table XXVI. It is 4 in. Let the distance from the outside of the web of the channel to the center of the bracket riveted to the web of the channel be 2 in, the projection of the bracket being 4 in; then x, the lever-arm of the moment of the load P_1, or the eccentricity, is 4 in + 2 in = 6 in. M, therefore, is P_1x or 30 000 lb × 6 in. c is 7 in, since the plates are 14 in wide. $I_{2-2} = 415$. Substituting in Formula (18)

$$S = \frac{164\,000 + 30\,000}{22.56} + \frac{30\,000 \times 6 \times 7}{415} = 8\,600 + 3\,036 = 11\,636 \text{ lb per sq in}$$

As this exceeds the safe unit fiber-stress of 10 245 lb per sq in, the column-section is too small.

For a second trial, consider a 12-in, 20.7-lb channel-column with 14 by ½-in plates. For this section, $I_{2-2} = 473$, $A = 26.06$ sq in, $r_{2-2} = 4.26$ in and $l/r = 384/4.26 = 90$.

$$S = \frac{12\,500}{1+(90)^2/36\,000} = \frac{12\,500}{1+8\,100/36\,000} = \frac{12\,500}{44\,100/36\,000}$$

$$= \frac{12\,500 \times 36\,000}{44\,100} = 10\,204 \text{ lb per sq in.}$$

The actual stress from Formula (18), as before, is

$$S = \frac{164\,000 + 30\,000}{26.06} + \frac{30\,000 \times 6 \times 7}{473} = 7\,444 + 2\,664 = 10\,108 \text{ lb per sq in}$$

As this is less than the safe stress of 10 204 lb, the second selection is safe.

Example 12. A Bethlehem H column 14 ft long carries 90.56 tons, of which 15.52 tons are eccentric, being applied to the flange of the column as shown in Fig. 27, the distance from the outside of the flange to the center of the bearing being 2 in. What is the size of the column required?

Try a 12-in, 84.5-lb column, which, for a length of 14 ft, or 168 in, will carry 161.4 tons (Table XX). For this column, $A = 24.92$, $r_{2-2} = 3.03$, $I_{1-1} = 676.1$, $I_{2-2} = 228.5$ and l is 14 ft, or 168 in; hence $l/r = 168/3.03 = 55$. Substituting in Formula (15), assuming that that formula is specified, $S = 15\,200 - 58 \times 55 = 12\,010$ lb per sq in. Since the eccentric load causes bending in a direction at right-angles to the axis 1-1, Fig. 27, the bending moment due to the eccentric load is P_1, or 15.52 tons or 31 040 lb, multiplied by its lever arm x, which is the distance from the axis 1-1 to the outside of the flange plus the distance from this surface to the center of bearing. The former dimension, taken from the Bethlehem Catalogue, is 6⅛ in and the latter is 2 in; hence $x = 8⅛$ in or for convenience, 8 in. The distance, c, also, of the outermost fiber from the axis

1–1 is 6¹⁄₁₆ in, which for convenience will be considered 6 in. I_{1-1} about th axis 1–1 is 676.1. Substituting in Formula (18), $S = (150\,080 + 31\,040)/24.92 +$ $(31\,040 \times 8 \times 6)/676.1 = 7\,268 + 2\,204 = 9\,47$ lb per sq in. As this is far below the sa stress of 12 010 lb, the column selected too large, and a smaller one, probably a 12-i 64.5-lb column would prove sufficient.

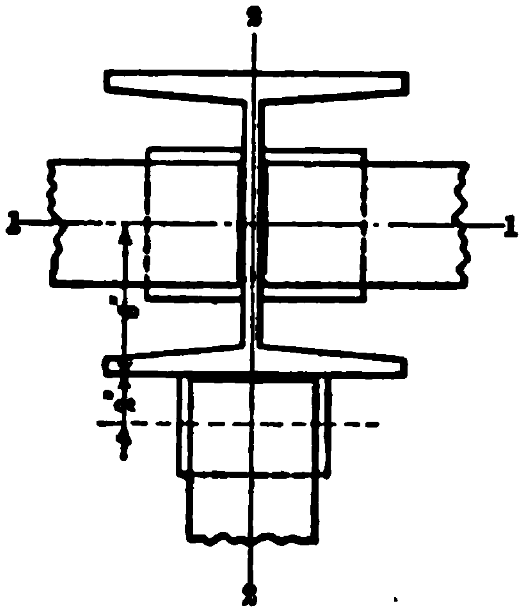

Fig. 27. Bethlehem H Column with Eccentric Load

Suppose, on the other hand, the eccentr load were applied to the web and the balanc loads to the flanges. The safe unit fibe stress, as before, is 12 010 lb per sq in, fo no matter how the loads are applied, the sa unit stress determined by reference to t least radius of gyration, r_{2-2}, should not b exceeded. Under the second condition loading the eccentric load, also, will cau bending about this same axis 2–2; hence Formula (18) the I for this axis, which 228.5, must be used. $x = 2$ in + 0.25 in 2.25 in, 0.25 in being one-half the thickne of the web. (See the Bethlehem Catalogue.) Hence, from Formula (18), t actual unit fiber-stress is $S = (150080 + 31\,040)/24.92 + (31\,040 \times 6 \times 2.25)/228$ $= 7\,268 + 1\,835 = 9\,103$ lb per sq in.

16. Tables of Safe Loads for Steel Columns

Safe Loads per Square Inch of Metal-Area for Steel Columns a Struts. To lessen the labor of calculating the strength of steel columns a struts, of whatever shape, the author has computed Table XI, which gives SA VALUES of S for ratios of l/r varying from 30 to 120. For ratios of l/r which a not whole numbers, the values can be readily interpolated. The values in t table should correspond exactly with the results obtained by using the corr sponding formulas.

Safe Loads for Steel-Pipe Columns. Tables XII and XIII give the SA LOADS for STEEL-PIPE COLUMNS. These loads are based upon the formula reco mended by the New York and Chicago Codes, $S = 16\,000 - 70\,l/r$. (See Ste Pipe Columns, pages 469 to 474.)

Safe Loads for Channel and Angle-Struts. Tables XIV, XV and X give the SAFE LOADS for standard CHANNELS and ANGLES used as STRUTS. On those sizes that are most commonly used are given. In Table XIV the SA LOADS for both the minimum and the maximum RADIUS OF GYRATION are give If the strut is used also as a beam, or is stayed so that it cannot bend sidewi the larger value may be taken; but if free to bend in either direction, then t smaller value should be taken. If the struts are subjected to a TRANSVER STRESS they should be computed as explained under the heading Strut-Bean pages 571 and 572.

Safe Loads for Steel-Beam Columns, Bethlehem Columns, Lally C umns, Plate-and-Angle and Channel Columns. Tables XVII to XXV giving the SAFE LOADS for these columns, were not computed by the auth but by the different manufacturers; they are, however, believed to be perfec safe, provided that an increase in area is made for ECCENTRIC LOADS.

Use of Table XI for Determining Safe Loads for Steel Column This table will be found of great assistance in calculating the strength of c

sions and of struts and also in making calculations for eccentric loads. To use it to find the strength of a column, it is merely necessary to multiply the value corresponding to the SLENDERNESS-RATIO of the column, by the SECTION-AREA, the result being the SAFE LOAD the column can support. As an illustration of this, the column considered in Example 8 has a slenderness-ratio of 63 and a section-area of 29.44 sq in. Its strength is to be calculated by the Chicago Building Code formula, the results of which are tabulated in the sixth column of Table XI. From this the value of a slenderness-ratio of 63 is 11 590 lb per sq in. Therefore, by the rule stated above, the safe load is 11 590 lb per sq in × 29.44 sq in = 341 209 lb. In Example 10, the column in the Bankers' Trust Company Building has a slenderness-ratio of 34.3, and an area of 351.5 sq in. The value corresponding to 34, from column 5 of Table XI, is 13 228 and for 35 it is 13 170 lb per sq in; hence for 34.3 it would be about 13 211 lb per sq in. Accordingly, the safe load is 13 211 lb per sq in × 351.5 sq in = 4 643 666 lb. Column 5 of Table XI gives values for old New York code.

Example 13. What is the safe resistance of a strut composed of two 5-in 9-lb channels, separated ¾ in and free to bend in either direction, the length of the strut being 7 ft 6 in?

Solution. From Table XVIII, page 374, the least radius of gyration for this section is 1, hence $l/r = 90/1 = 90$. From the eighth column of Table XI, the value of S opposite 90 is 8 000 lb per sq in; the safe load, then, is equal to 8 000 lb per sq in, multiplied by the area of the two channels, 5.26 sq. in, or 42 080 lb.

Example 14. What is the safe stress for a 7-in 15.5-lb I beam when used as a strut? It is 90 in in length and free to bend in either direction.

Solution. From Table IV, page 355, the least radius of gyration of this section is 0.78, and the area is 4.43 sq in. $l/r = 90/0.78 = 115.4$. From the eighth column of Table XI, the value opposite 115 is 6 750 and opposite 116 it is 6 700 lb per sq in; so for 115.4 it would be about 6 730 lb per sq in. The safe load, therefore, is 6 730 lb per sq in × 4.43 sq in = 29 814 lb.

By means of the tables and rules given in Chapter X the SECTION-AREA and LEAST RADIUS OF GYRATION of any standard section or any combination of sections may be found; and once these are determined the strength of a strut or column may be readily computed, as in the above examples.

Use of Table XI for Eccentric Loads for Steel Struts. As an illustration of its application to determine eccentric loads, refer again to Example 11. The value of l/r for this column is 89. The safe unit fiber-stress was found to be, by Formula (11), 10 245 lb per sq in. The practically identical result can be obtained by looking for the value opposite 89 in column 2 of Table XI. It is found to be 10 250 lb.

Proportion of Floor-Loads Borne by Columns. (See, also, pages 148 to 152.) In tall buildings it is customary to reduce the COLUMN-LOADS somewhat from the loads used in calculating the floor-beams. This is done on the theory that it is quite impossible for the entire floor-area of every story to be loaded to the maximum limit at the same time. For all buildings except warehouses it would seem, in general, to be good practice to design the columns to carry all the DEAD LOAD and 75% of the assumed LIVE LOAD. Of course city laws vary in these requirements. Thus, if in an office-building, the dead load, or weight of the floor-construction, is 80, and the live load 80 lb per sq ft, the load on the columns would be 80 + 60 = 140 lb per sq ft times the floor-area supported by the column. In some cases the reduction might be even greater, depending upon the live load assumed and the position of the column in the building, the reductions being greater in the lower than in the upper stories.

The Building Code of New York City specifies that for buildings exceedi five stories in height the COLUMN-LOADS shall be made up as follows: For t roof and top floor the full live loads shall be used; for each succeeding low floor it shall be permissible to reduce the live load by 5% until 50% of the li load is reached, when such reduced loads shall be used for all remaining floo (For assumed loads for office-buildings, required by the building codes of se eral cities, see page 151).

Column-Sheets. In a high building the COLUMN-LOADS vary to such extent and are made up of so many elements, that to avoid omissions and err it is necessary to make a TABULATED LIST of all the loads transferred throu the columns to the footings. In a building of skeleton construction the COLUM LOADS include floor and roof-loads, wind-loads, spandrel and pier-loads, t weight of the columns themselves and their fire-proof covering, and in some ca special loads, such as tanks, vaults, safes and elevator-loads. In tabulati the FLOOR-LOADS it is advisable to separate the dead and live loads for c venience in proportioning the footings. (See, also, pages 148 to 160.) Formu for computing the WIND-LOADS on columns are given in Chapter XXIX; th loads, also, are considered as live loads. ECCENTRIC LOADS should always tabulated separately from the balanced column-loads. On page 491 is sho a form of COLUMN-SHEET which combines all ordinary requirements. T TOTAL LOAD for each story is the sum of all of the loads above. The SCHEDU on page 492 shows a very convenient form for column-lengths and column-pa

Important Notes Regarding Safe Loads on Columns. (See pages 504 a 505, and 517 to 554.) "For ratios of l/r up to 120 and for greater ratios up 200, use the values given in the following table for the allowable stress pounds per square inch. For intermediate ratios, use proportional amounts.

Ratio	Amount	Ratio	Amount
60	13 000	130	6 500
70	12 000	140	6 000
80	11 000	150	5 500
90	10 000	160	5 000
100	9 000	170	4 500
110	8 000	180	4 000
120	7 000	190	3 500

"(5). For bracing and combined stresses due to wind and other loadi the permissible working stresses may be increased 25 per cent, provided section thus found is not less than that required by the dead and live lo alone.*

"(6). General. The effective or unsupported length of main compressi members shall not exceed 120 times, and for secondary members 200 times, least radius of gyration."*

The values for ratios of l/r above 120 are computed from the formula

$$S = 13\,000 - 50\, l/r,$$

but the important condition should be observed, that for l/r above 120, co pression-members should never be used for main members but only as second members subject to wind-stresses, etc. (See, also, page 495 for maximum ra of l/r for main members and for secondary members, such as bracing struts, et

Comparative Diagram of Compression-Formulas

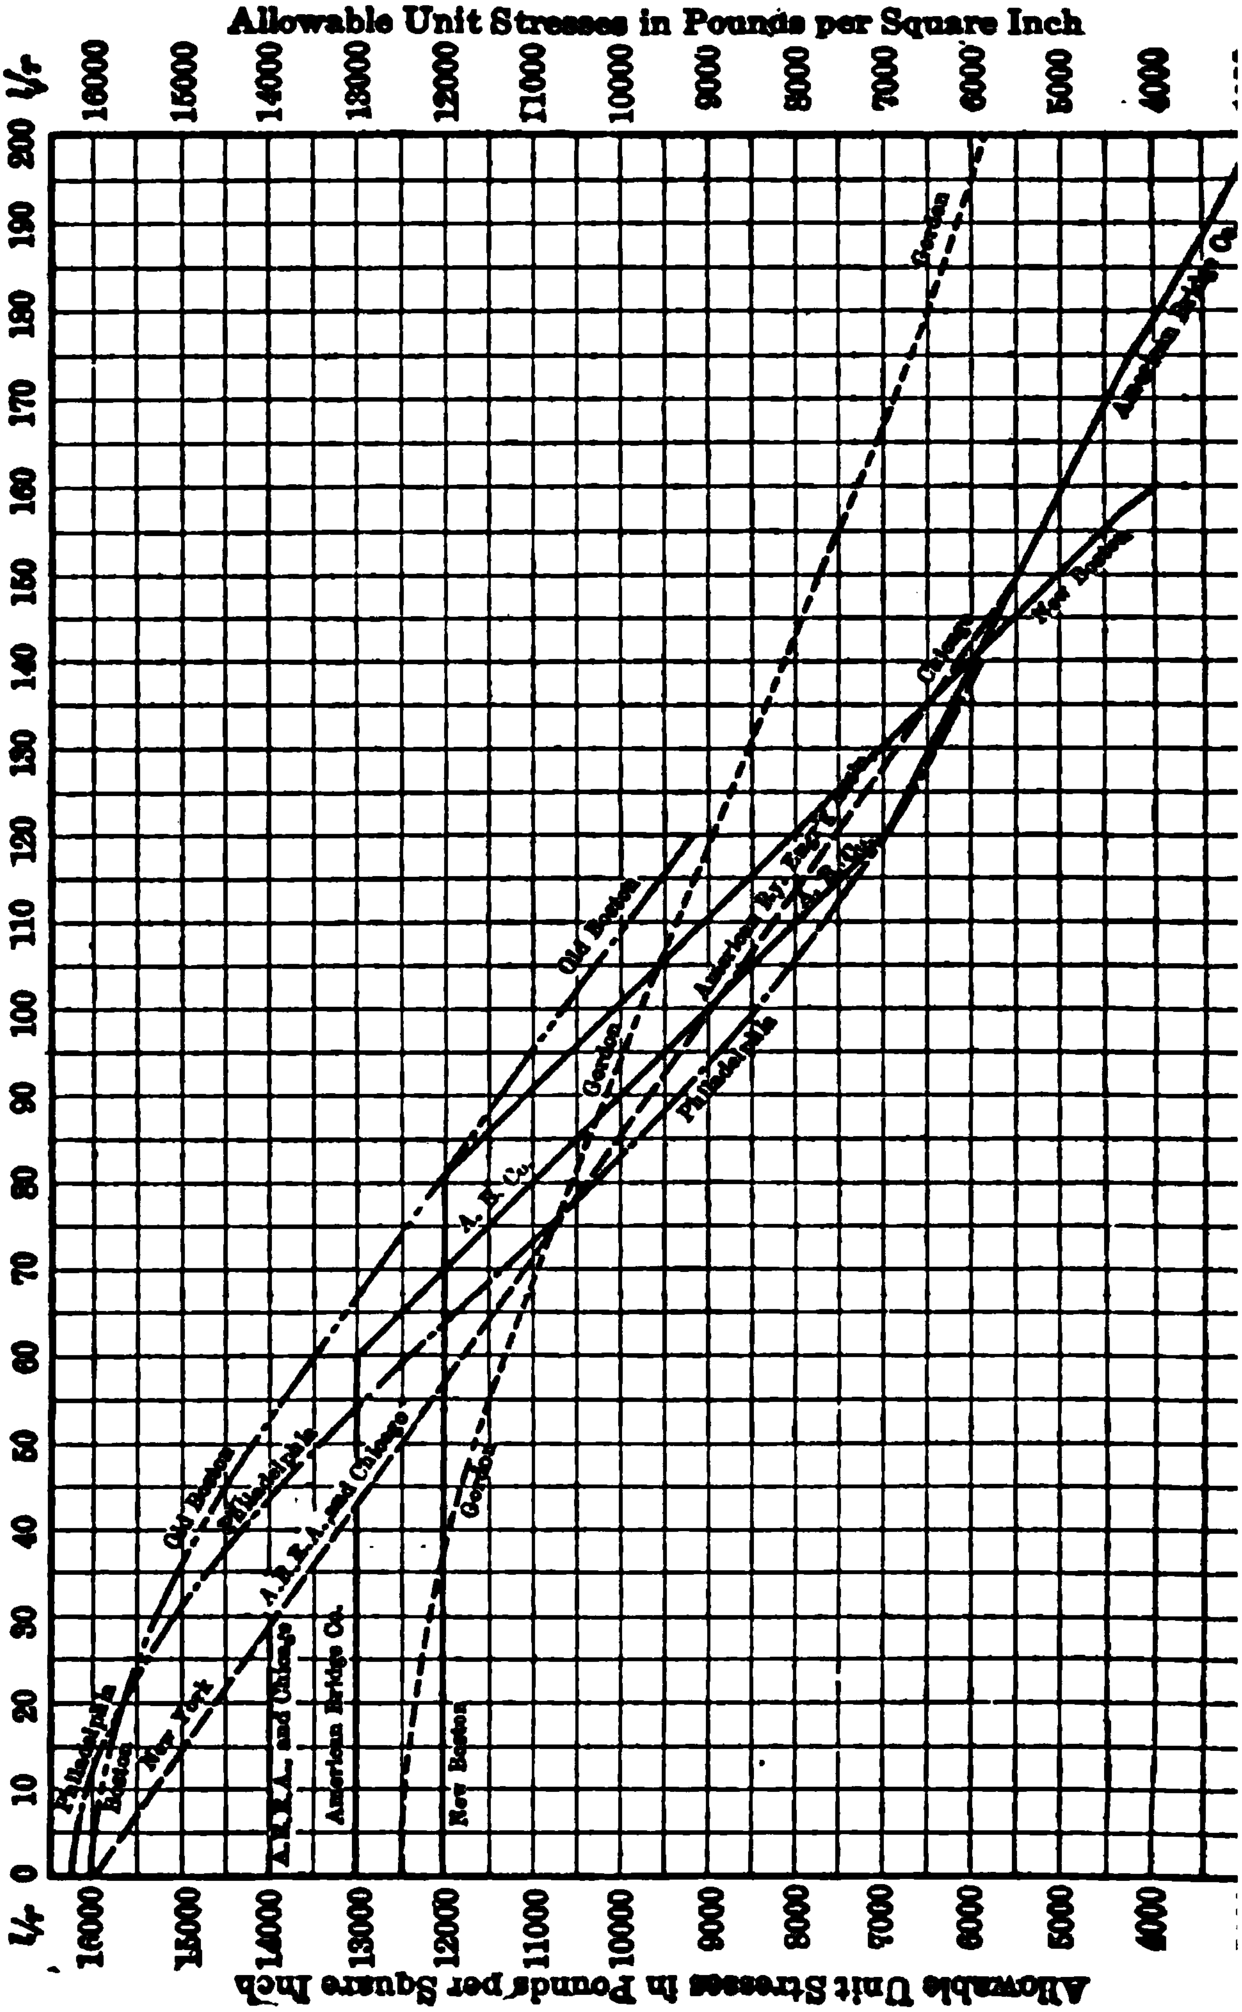

Table XII.* Safe Loads in Tons of 2 000 Pounds for Standard Steel-Pipe Columns. See National Tube Company's Handbook for Values of r Used

Loads in tons of 2 000 pounds. Table based on New York and Chicago laws. Formula used, $S = 16\,000 - 70\, l/r$, in which

S = allowable compressive stress for steel in pounds per square inch,
l = length of column in inches,
r = least radius of gyration in inches.

Loads above or to the left of the zigzag lines correspond to values of l/r greater than 120.

Table XXII. Safe Loads in Tons of 2 000 Pounds for Light-Weight L Columns *

Factor of safety between 4.5 and 5

Calculated by the formula, $P = A_s(13\ 500 - 140\ l/d) + A_c(1\ 000 - 11\ l/d$

in which A_s and A_c are the areas of steel pipe and concrete, in square inches, length in inches, and d the outside diameter of pipe, in inches

Outside diameter, in	Weight per linear foot, in	Length of column in feet

Table XXIII. Safe Loads in Tons of 2 000 Pounds for Heavy-We Lally Columns*

Factor of safety between 4.5 and 5

These loads can be greatly increased by reinforcing the concrete

Calculated by the formula, $P = A_s(13\ 500 - 140\ l/d) + A_c(1\ 000 - 11\ l/$

in which A_s and A_c are the areas of steel pipe and concrete, in square inches, length in inches, and d the outside diameter of pipe, in inches

Outside diameter, in	Weight per linear foot, lb	Length of columns in feet

The safe load-values above the upper heavy line are for ratios of l/r not over 60; those between the heavy lines are for ratios up to 120 l/r; and those below the lower heavy line are for ratios not over 200 l/r

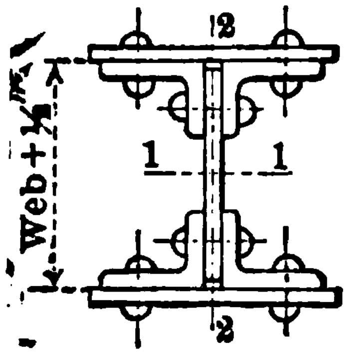
* From Pocket Companion, Carnegie Steel Company, Pittsburgh Pa.

Table XXIV* (Continued). Safe Loads in Units of 1 000 Pounds for Plate-and-Angle Columns



Allowable fiber-stress in pounds per square inch:
13 000 for lengths of 60 radii or under
Reduced for lengths between 60 and 120 radii, by Formula (13).

$$S = 19\,000 - 100\,l/r$$

Weights do not include rivet-heads or other details
For values for l/r above 120, see notes on page 490

CHAPTER XV

STRENGTH OF BEAMS AND BEAM GIRDERS. FRAMING AND CONNECTING STEEL BEAMS

By
CHARLES P. WARREN
LATE ASSISTANT PROFESSOR OF ARCHITECTURE, COLUMBIA UNIVERSITY

1. General Principles of the Flexure of Beams

Definitions. A structural member placed in a generally horizontal position upon two or more supports or projecting from some other construction is called a BEAM. A GIRDER is a beam carrying smaller or secondary beams. A CANTILEVER BEAM is a beam supported at the middle, or having one end fixed, as in a wall, and the other end free; or it is the part of a beam which overhangs, or projects, beyond a support. A SIMPLE BEAM is one which rests upon two supports, one at each end. A CONTINUOUS BEAM rests upon more than two supports. The distance between the supports of a simple beam, or, when so specially designated from center to center of the bearings, is the SPAN. It is usually designated by l. The loads on beams are either UNIFORMLY DISTRIBUTED or CONCENTRATED. A uniformly distributed or UNIFORM load includes the weight of the beam itself and any load spread evenly over it, such as the weight of a wall. Uniform loads are estimated by their intensity per unit of length of the beam, in pounds per linear foot. A uniform load per linear foot is represented by w, and the total uniform load by wl or W. A concentrated load is a single applied weight, such as a column and its load, or the load from another beam, and is designated by P.

Stresses and Deformations. A load on a simple beam causes the fibers to bend or deflect, and eventually to break across, or in other words, a load induces TRANSVERSE OR FLEXURAL STRESSES in the fibers. Since it is impossible to bend or deflect a simple beam without causing a shortening of the fibers on the upper or concave side and an elongation of the fibers on the lower or convex side, a load on a beam causes COMPRESSION in the upper fibers and TENSION in the lower fibers, while between the two there is a neutral layer or surface of fibers which is unchanged in length and which is called the NEUTRAL SURFACE of the beam. In a cantilever beam the reverse is the case, the upper fibers being in tension and the lower ones in compression.

Laws Determined by Experiment. From experiments it has been found that the amount of elongation or shortening of any fiber is directly proportional to its distance from the neutral surface of a beam; hence, if the ELASTIC LIMIT is not exceeded, the stresses, also, are proportional to their distances from the neutral surface. The trace of the neutral surface on a cross-section of a beam is called the NEUTRAL AXIS of the cross-section. Within the elastic limit of a material the neutral surface passes through the CENTERS OF GRAVITY of the cross-sections of a beam for all materials.

Bending Moments and Resisting Moments.* To determine the strength of any beam to resist the effects of any load or series of loads, two things must

* See, also, Chapter IX, pages 324 to 331.

be determined: first, the moment or moments of the external destructive fo or forces tending to bend and break the beam, which is called the MAXIM BENDING MOMENT; and, secondly, the moments of the combined resistance all the fibers in the DANGEROUS SECTION of the beam to being broken, wh in their summation, are called the MOMENT OF RESISTANCE or the RESIST MOMENT.

The Methods of Finding the Bending Moments for any load or se of loads are explained in Chapter IX. The moment of resistance is equa the SECTION-MODULUS or SECTION-FACTOR, denoted by I/c, multiplied by unit stress on the outermost fiber of the material, denoted by S, and it eq the bending moment.

Hence $$M = SI/c$$

This is known as the FLEXURE-FORMULA and it is the fundamental formula designing beams. Formulas for finding the section-moduli of common sh are given in Chapter X, and the values of I/c or the section-moduli of standard rolled shapes, are given in the tables in the same chapter.

The Coefficient of Strength,* sometimes given in tables of steel beam the maximum distributed load that a beam of one foot span would sup without producing a fiber-stress exceeding the safe limit, generally 16 oo per sq in. As the strength of a beam varies inversely as its span, the safe for any span may be obtained by dividing this coefficient by the span in fee

Factors of Safety. In order that a beam shall just be able to carry a and not break, that condition of equilibrium must exist, in which the m mum bending moment in the beam is equal to the section-modulus multi by the ultimate strength of the material. In order that a beam may abundantly SAFE to carry a given load, the product of the section-modulu the ultimate strength of the material must be several times greater than maximum bending moment; and the ratio which this product bears to maximum bending moment, or which the BREAKING-LOAD bears to the s LOAD, is known as the FACTOR OF SAFETY, that is,

$$\text{Factor of safety} = \frac{\text{ultimate strength}}{\text{working stress}}$$

Ultimate Strengths and Safe Fiber-Stresses. By the STRENGTH OF MATERIAL is meant a certain constant quantity which is determined by ex ment, and which is known as the ULTIMATE BREAKING STRENGTH. value is of course different for each material. Table I gives the values of constant divided by the factor of safety, or in other words, the WORKING ST for most of the materials used in building-construction. The section-m multiplied by these values will give the SAFE RESISTING MOMENTS for the be The values of S in Table I for steel are about one-fourth those of the break loads; for cast iron, about one-sixth; for average specimens of wood, one-s and for stone and concrete, one-tenth. The safe compressive strength of iron for the compression-side of beams is 16 000 lb per sq in, in the New Building Code. This is considered too high by some engineers and the au recommends 10 000 lb per sq in. This value has been used in calculating safe loads for cast-iron columns. (See Chapter XIV, page 461.) The loads for the steel shapes given in the tables in this chapter are all comp

* The values for coefficients of strength have been omitted from most of the t following the policy of some of the latest handbooks, as the safe loads for beam example, can be as readily determined from the data of the tables directly, as b process of dividing such coefficients by the spans. See, however, pages 586 to 59 623 to 628.

the value of 16 000 lb per sq in for S, but these full loads should be used h caution, and reduced when necessary to satisfy any unusual conditions. r riveted steel girders 14 000 lb per sq in was the value formerly given to S, t the usual value now is 16 000 lb per sq in.

Table I. Safe Unit Fiber-Stresses, S, for Flexure of Beams *

s to be noted that these are average values, especially those for wood. For allowable higher stresses for timber, see also, notes on pages 628, 637 and 647.

Materials Wood unseasoned †	Values of S, lb per sq in	Materials Wood unseasoned †	Values of S, lb per sq in

† For a comparison of values given in different building laws see Table XVII, page 648, pter XVI. Compare, also, with Table XVI, page 647, Chapter XVI. For ultimate es for woods, see Tables XVIII and XIX, pages 650 and 651, Chapter XVI. For loads for unit beams, see Tables II and III, page 628, Chapter XVI.

Add from 30 to 40% for seasoned, protected timber, used without impact.

ams Unsymmetrically Loaded or of Irregular Cross-Section. There ertain loadings and cross-sections of beams that occur most frequently in ing-construction, and for which tables have been worked out that give the loads directly; but for a beam unsymmetrically loaded, or for a beam of ular cross-section, it is impossible to compute tables for strength, as in each the values must be computed by determining either the section-modulus, quired to resist the maximum bending moment, or the maximum bend-oment that may be allowed for a given value of the section-modulus.

eral Formulas for the Flexure of Beams.* The general formula for eam in a state of flexure under any system of loading is

Maximum bending moment in INCH-POUNDS = section-modulus × S (2)

$$M_{\max} = SI/c \qquad (2)'$$

$$\text{Section-modulus} = \frac{\text{maximum bending moment in in-lb}}{S} \qquad (3)$$

$$I/c = M_{\max}/S \qquad (3)'$$

* See, also, Chapters IX, X and XVI.

If the bending moment is computed in FOOT-POUNDS, these formulas beco

$$\text{Maximum bending moment} = \frac{\text{section-modulus} \times S}{12}$$

or

$$M_{max} = SI/12\,c$$ (

and

$$\text{Section-modulus} = \frac{12 \times \text{maximum bending moment}}{S}$$

or

$$I/c = 12\,M_{max}/S$$ (

By substituting for the bending moments their values in terms of the lo and the spans, the following formulas which apply to beams of any cross-sect are readily deduced.

2. Formulas for Safe Loads for Beams for Different Conditions of Loading and Support

I/c = the section-modulus,
S = the safe unit fiber-stress in pounds per square inch;
W = the total uniform load in pounds;
P = the concentrated load in pounds;
l = the span in feet.

Values of I/c for the various shapes and sizes of structural-steel shapes given in the tables of Chapter X.

Case I

Beam Fixed at One End and Loaded with a Concentrated Load P, Near the I End (Fig. 1).

From Formula (4)′,

$$M_{max} = SI/12\,c$$

From Case I, Chapter IX,

$$M_{max} = Pl$$

Hence

$$Pl = SI/12\,c$$

and the safe load in pounds is

$$P = SI/12\,cl$$

and the section-modulus is

$$I/c = 12\,Pl/S$$

Fig. 1. Cantilever Beam. Load near Free End

Example 1. A steel T bar is fixed at one end in a brick wall, and loade the other end with 600 lb, the distance l being 4 ft. What is the size of the required to support the load with safety? (In all examples the weights of beams are neglected, unless particularly mentioned.)

Solution. Allowing 16 000 lb per sq in for the value of S, Formula (6)′ ,

$$I/c = (12 \times 600 \times 4)/16\,000 = 1.8$$

The next step is to ascertain what T bar has a section-modulus equal tc In Table XIV, page 369, the nearest section-modulus to this is 1.9, corresp ing to a 3 by 4 by ½-in T bar.

For an I beam, by Table IV, page 355, $I/c = 1.8$, the same as for the T and calls for a 3-in 6.5-lb I beam.

Case II

...m Fixed at One End and Loaded with a Uniformly Distributed Load W (...g. 2).

...rom Formula (4)′

$$M_{max} = SI/12c$$

...m Case II, Chapter IX,

$$M_{max} = Wl/2$$

...nce

$$Wl/2 = SI/12c$$

... the safe load in pounds is

$$W = SI/6cl \qquad (7)$$

...d

$$I/c = 6Wl/S \qquad (7)'$$

Fig. 2. Cantilever Beam. Distributed Load over Entire Span

...ample 2. What is the size of a can...ver steel I beam required to carry a uniformly distributed load of 150 lb per ...over a length of 6 ft?

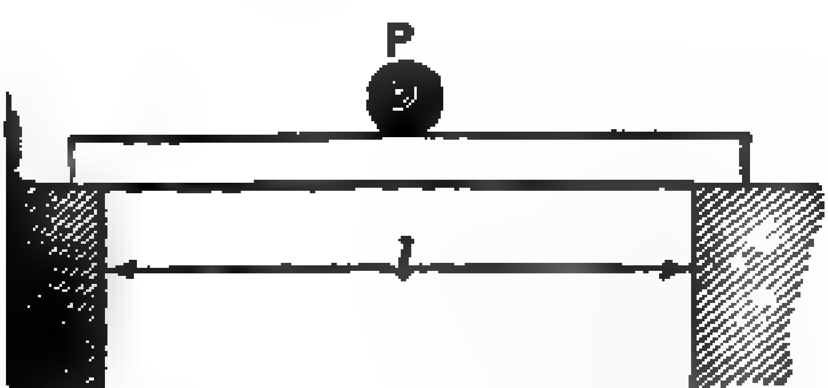
...lution. $W = 150 \times 6 = 900$ lb. Substituting in Formula (7)′,

$$I/c = \frac{6 \times 900 \times 6}{16\,000} = 2.025$$

... Table IV, page 355, the nearest section-modulus to this is 1.9, which is ...t of a 3-in 7.5-lb beam, the heaviest of that depth. However, as the ...est 4-in beam, also, weighs 7.5 lb per ft it probably would be selected be...se of its greater stiffness, although its section-modulus is 3, still greater ...n required.

Case III

...m Supported at Both Ends and Loaded with a Concentrated Load at the ...ddle (Fig. 3).



...g. 3. Simple Beam. Load at Middle of Span

From Formula (4)′

$$M_{max} = SI/12c$$

From Case IV, Chapter IX,

$$M_{max} = Pl/4$$

Hence

$$Pl/4 = SI/12c$$

and the safe load in pounds is

$$P = SI/3cl \qquad (8)$$

and

$$I/c = 3Pl/S \qquad (8)'$$

...ample 3. What steel I beam will safely support a concentrated load of ...ns applied at the middle of a 15-ft span?

...lution. $P = 7$ tons $= 14\,000$ lb. Substituting in Formula (8)′,

$$I/c = \frac{3 \times 14\,000 \times 15}{16\,000} = 39.3$$

...ing again to Table IV, page 355, it is seen that a 12-in 35-lb beam has

a section-modulus of 37.8, while a 12-in 40.8-lb beam, the next larger has a section-modulus of 44.8. The 35-lb beam, however, would undoubt be safe.

Case IV

Beam Supported at Both Ends and Loaded with a Uniformly Distributed (Fig. 4).

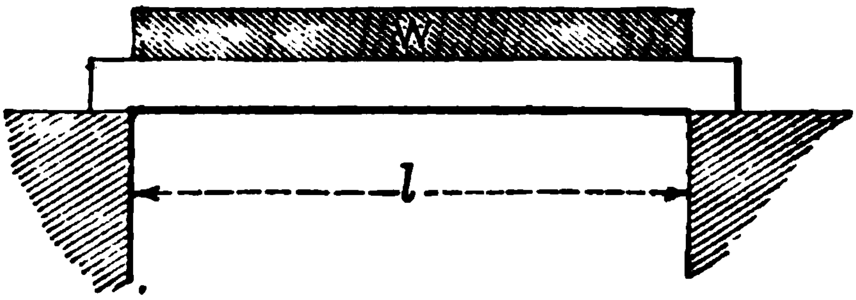


Fig. 4. Simple Beam. Distributed Load over Entire Span

From Formula (4)'

$$M_{max} = SI/12c$$

From Case V, Chapter IX,

$$M_{max} = Wl/8$$

Hence

$$Wl/8 = SI/12c$$

and the safe load in pounds is

$$W = 2SI/3d$$

and

$$I/c = 3Wl/2S$$

Example 4. What steel I beam will safely carry a uniformly distribute of 1 000 lb per ft over a span of 25 ft?

Solution. $W = wl = 1\,000 \times 25 = 25\,000$ lb. Substituting in Formula

$$I/c = \frac{3 \times 25\,000 \times 25}{2 \times 16\,000} = 58.6$$

From Table IV, page 354, the nearest section-modulus is 58.9, which is t a 15-in 42.9-lb beam.

Case V

Beam Supported at Both Ends and Loaded with a Distributed Load Over of the Span (Fig. 5).

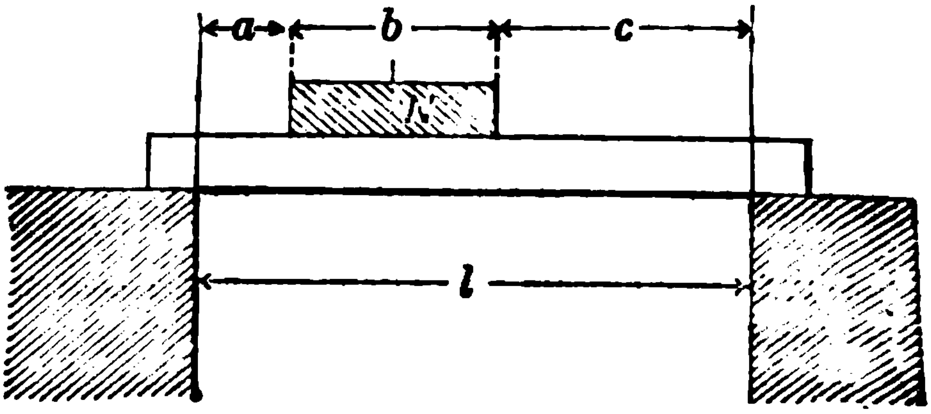

Fig. 5. Simple Beam. Distributed Load over Part of Span

In this case the load is generally given, and the problem is to determ size of the required beam. This can be done accurately only by com

maximum bending moment as explained for Case VIII, Chapter IX, and substituting the value thus found in Formulas (3)′ or (5)′.

Example 5. What steel I beam will safely carry a uniformly distributed load of 1 200 lb per ft over part of the span, beginning at a point 5 ft from the left reaction and extending over a distance of 6 ft, the span of the beam being 18 ft?

Solution. The first step is to find the point of maximum bending moment, which is the point of no shear. Obviously the maximum shear is just at the right of the reaction nearest the load, which in this case is the left reaction. To find the left reaction (see Chapter IX, page 324) the center of moments is taken at the right reaction and the equation of moments is $R_1 \times 18$ ft $-$ (1 200 lb $\times$ 6 ft) $\times$ 10 ft $= 0$. $18\,R_1 = 72\,000$ and $R_1 = 4\,000$ lb. The shear just at the right of R_1 is therefore $+4\,000$ lb which, if the weight of the beam itself is not considered, remains unchanged for every section of the beam between the left reaction and the uniformly distributed load of 1 200 lb per ft. From there on in passing to the right, the shear is diminished at the rate of 1 200 lb per ft; and it becomes zero, therefore, at a point 4 000 lb/1 200 lb per ft = 3.3 ft to the right of the 5-ft point. Hence the point of no shear and consequently the point of maximum bending moment is at 5 ft + 3.3 ft, or 8.3 ft, from the left end. The equation for the maximum bending moment at this point is, therefore,

$$M_{max} = 4\,000 \text{ lb} \times 8.3 \text{ ft} - (1\,200 \text{ lb} \times 3.3 \text{ ft}) \times 3.3/2 \text{ ft}$$
$$= 33\,200 \text{ ft-lb} - 6\,534 \text{ ft-lb} = 26\,666 \text{ ft-lb, or } 319\,992 \text{ in-lb}$$

From Formula (3), $I/c = 319\,992$ in-lb/16 000 lb per sq in $= 20$. From Table V, page 355, the nearest section-modulus corresponding to this is 20.3, that of a 9-in 25-lb beam. A 10-in 25.4-lb beam, however, being stronger and stiffer, would probably be used. The 10-in 22.24-lb beam is what is termed a SUPPLEMENTARY BEAM. (See Case VIII, Chapter IX, and pages 352 and 353.)

Case VI

Beam Supported at Both Ends and Loaded with a Concentrated Load, not at the Middle (Fig. 6).

Fig. 6. Simple Beam. Concentrated Load at any Point

From Formula (4)′,

$$M_{max} = SI/12c$$

From Case VI, Chapter IX,

$$M_{max} = Pmn/l$$

Hence

$$Pmn/l = SI/12c$$

The safe load in pounds is

$$P = SIl/12\,cmn \qquad (10)$$

$$I/c = 12\,Pmn/lS \qquad (10)'$$

m, n and l being in feet.

Example 6. A steel I beam 20 ft in span is to support a concentrated lo 24 000 lb at a distance of 6 ft from the left support. What must be th and weight of the beam?

Solution. In this case $P = 24\,000$ lb, $l = 20$ ft, $m = 6$ ft, $n = 14$ ft and 16 000 lb per sq in.

Then Formula (10)′ gives

$$I/c = \frac{12 \times 24\,000 \times 6 \times 14}{20 \times 16\,000} = 75.6$$

Table IV, page 354, the nearest value for the section-modulus I/c fo 1–1 is above 75.6, or 81.2 for a 15-in 60.8-lb beam. An 18-in 55-lb beam h a section-modulus of 88.4 would be used, unless conditions fix the head- as it weighs 5 lb per ft less, and being deeper is consequently stiffer.

Case VII

Beam Supported at Both Ends and Loaded Symmetrically with Two Concentrated Loads (Fig. 7).

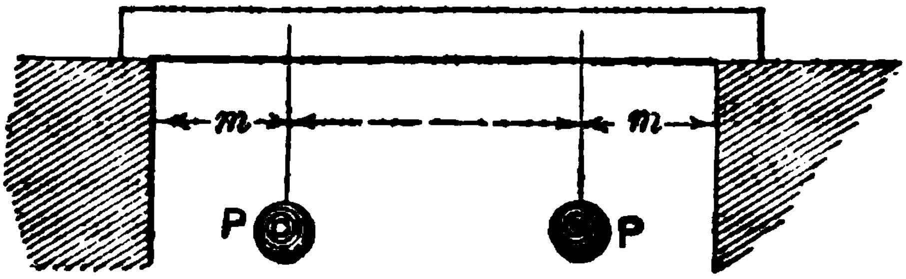

Fig. 7. Simple Beam. Equal Concentrated Loads Symmetrically Placed

From Formula (4)′ and Case VII, Chapter IX, each of the safe loads in p is

$$P = SI/12\,cm$$

and

$$I/c = 12\,Pm/S$$

Example 7. A 12-in steel channel, 12 ft in span, supports half the lo two 10-in beams 4 ft from each end. Each beam is designed to carry 16 o What is the size and the weight of the channel required?

Solution. The channel supports only one-half the load on each beam; $P = 8\,000$ lb, $m = 4$ ft, $S = 16\,000$ lb per sq in, and by Formula (11)′,

$$I/c = \frac{12 \times 8\,000 \times 4}{16\,000} = 24,$$

which is the section-modulus of a 12-in 25-lb channel. (See Table page 359.) Exact table-value, 23.9.

Weights of Beams in Flexure-Formulas. It will be noticed that i mulas (11) and (11)′ the span of the beam is not taken into account, and beam itself had no weight there would be no difference in the fiber-st no matter how far apart the loads P were placed. In reality, however, beams have considerable weight, and to be absolutely correct an example as the one above should include the weight of the beam, which would, of c be a uniformly distributed load. The maximum bending moment of the can be found graphically as explained on page 329, and the value of I/c puted by Formulas (3)′ or (5)′. Where, however, the loads are spaced to divide the beam into three equal parts, as in the last example, one-th the weight of the beam may be added to P with sufficient accuracy. Thu

ght of the channel in the above example between the supports would be lb × 12, or 300 lb, and P would be 8 100 lb, which would give a value for of 24.1. The factor of safety in the loads allowed is generally large enough offset the slight effect produced by the weight of the beam; but if the full d assumed is likely to be imposed on the beam, then allowance must be made the weight of the beam itself.

Case VIII

am Supported at Both Ends and Loaded Symmetrically with Several Con- ntrated Loads (Fig. 8).

In this case it is necessary to compute the maximum bending moment in the am and proportion the beam by Formulas (3)′ or (5)′.

Example 8. A steel-beam girder is to be designed to support a brick wall, in thick and weighing 138 000 lb, over an opening 22 ft wide. The girder t also support the ends four 10-in floor-beams ced as in Fig. 8, each m carrying 16 000 lb. hat is the size and weight the girder required?

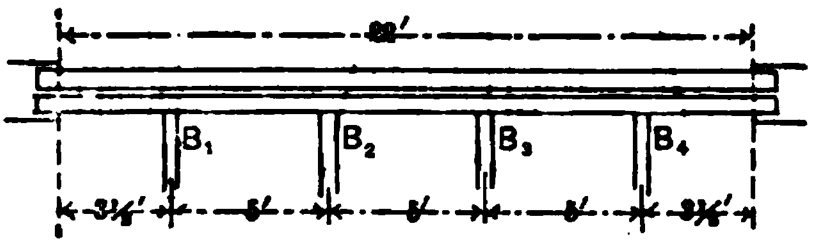

Fig. 8. Simple Beam. Several Concentrated Loads Symmetrically Placed

Solution. The first step to make an allowance for e weight of the girder. e total load on the girder (neglecting the weight of the girder itself) = 138 000 + 4 × 8 000 lb (one-half the load on each beam) = 170 000 lb, or 85 tons. this is much more than the heaviest single rolled beam will carry, it will be ssary to use a pair of beams and the load on each beam, therefore, will be tons. Considering for the present the entire load as uniformly distributed, le IV, page 577, shows that to support 42.5 tons, or 85 000 lb, over a span 2 ft requires a 24-in 85-lb beam. The girder then will weigh between sup- s 2 × 85 × 22 = 3 740 lb, or about 4 000 lb. This added to the weight of wall makes, for the total distributed load, 142 000 lb. The next step is to ermine the maximum bending moment.

By the formulas given in Chapter IX the maximum bending moments for various loads may be found as follows:

the wall and girder (Case V, page 326),

$$M_{max} = \frac{22 \times 142\,000}{8} = 390\,500 \text{ ft-lb}$$

the beam B_1 (Case VI, page 327),

$$M_{1\,max} = \frac{8\,000 \times 3\tfrac{1}{2} \times 18\tfrac{1}{2}}{22} = 23\,545 \text{ ft-lb}$$

the beam B_2 (Case VI, page 327),

$$M_{2\,max} = \frac{8\,000 \times 8\tfrac{1}{2} \times 13\tfrac{1}{2}}{22} = 41\,727 \text{ ft-lb}$$

e beams being spaced symmetrically from the middle of the span, the bend- oments for B_3 and B_4 will be equal to those of B_2 and B_1 respectively. ing the bending moments to a scale, in the manner explained for Figs. 17 page 330, the diagram shown in Fig. 9 is obtained. The greatest bend- oment is the ordinate M_x, which scales 486 500 ft-lb, or 5 838 000 in-lb.

Note. Since the loads are symmetrically placed, this ordinate is over middle point of the girder, but it is drawn to one side in the figure in order to confuse it with the ordinate M, the maximum bending moment for the formly distributed load. Substituting this value of M_x in formula (3)′,

$$I/c = \frac{5\ 838\ 000 \text{ in-lb}}{16\ 000 \text{ lb per sq in}} = 365$$

the section-modulus for both beams, or 182.5 for one beam. From Table page 354, it is found that a 24-in 90-lb beam has a section-modulus of 18 and two 90-lb beams will just ans The assumption of a uniform distribu of such a loading over every foot girder usually results in the selectio lighter beams than are indicated by second solution, in which each con trated load is considered as really centrated at a point. The two be should be securely bolted together separators near each connection of be B_1, B_2, B_3, B_4, and at each end of girder.

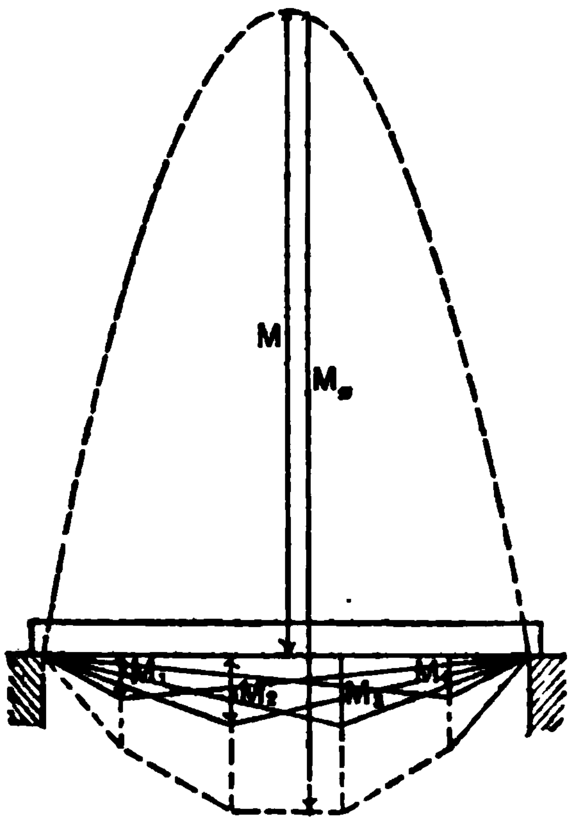

Fig. 9. Bending-moment Diagram for Beam Shown in Fig. 8.

A DOUBLE-BEAM GIRDER, however not considered the best kind of girde use under this condition of loading, as not good construction nor economica material. As a general rule BEAM DERS should be used only when the l can be applied to the upper flange both beams. Transferring a load dire to the web of one beam, even thoug is connected with the other beam means of separators, does not insur equal distribution of the loading. The author, therefore, recommends in case a RIVETED BEAM GIRDER or a RIVETED PLATE GIRDER. The method al indicated applies to any method of loading, the only difference in the culation being in the determination of the maximum bending moments.

Inclined Beams. The strength of beams inclined to the horizontal ma computed, with sufficient accuracy for most purposes, by using the form given for horizontal beams, and taking the HORIZONTAL PROJECTIONS of the b as the spans.

2. Steel Beams and Girders*

Materials Used for Beams. Practically the only materials used in s tural work for beams, at the present day, are wood, steel and reinforced conc As wooden beams are always rectangular in cross-section, the general form used in this chapter can be much simplified by substituting for I/c its val terms of the breadth and depth of the beam. Formulas for wooden beam therefore be found in Chapter XVI. Cast iron, also, is occasionally use beams or lintels, but as this material is much stronger in resisting compre than tension, the beam must be of a special shape in order to use the ma to advantage. The strength of cast-iron beams is therefore considered

* For the deflection of steel beams, see Chapter XVIII.

pecial heading in Chapter XVI. Formulas for reinforced-concrete beams are ven in Chapter XXIV, pages 924 to 939; and Chapter XXV, page 992.

Forms of Steel Beams. Since 1893, steel beams have superseded wrought-on beams, and the latter are now never used. Any shape of rolled steel may e used as a beam, but the I shape is the most economical, as it possesses the eatest resistance for a given weight of metal. Next to the I beam, in economy, the channel, then the deck beam; angles and tees are the least economical all shapes. The following values show the safe loads per pound of steel, for e various shapes, for a 10-ft span; the same ratio would hold for other spans.

10-in I beam	10-in channel	10-in deck-beam	4 by 6-in angle	4 by 5-in tee
104	94.6	83.0	28.7	21.6

The Deepest Beams, the Strongest, Stiffest and Most Economical. e STRENGTH of a wooden or steel beam of rectangular cross-section varies as e SQUARE OF THE DEPTH, directly as the breadth and inversely as the length, d the STIFFNESS varies directly as the CUBE OF THE DEPTH, directly as the adth and inversely as the cube of its length; hence the deeper beam will e the greater strength and stiffness in proportion to its sectional area. With eams these relations do not hold strictly, because of the variation in the ms of the cross-sections, but they are approximately true. It therefore ows that, for any given span, it is more economical in floors, where other ditions will permit, to use deep beams spaced farther apart or to use one deep m in place of two shallower beams. Thus if a distributed load of 39 tons o be supported over a span of 16 ft, one 20-in 65-lb beam, two 15-in 42-lb ms, or three 12-in 40-lb beams, could be used; but the 20-in beam would h only 1 105 lb, allowing for 6-in bearings, as compared with 1 428 lb for 15-in beams and 2 040 lb for the 12-in beams, and the bolts and separators ld be saved.

ight and Heavy Steel Beams. LIGHT BEAMS are more economical than vy beams OF THE SAME DEPTH, except when the span is so short that the load is governed by the resistance of the web to buckling, in which case the VY BEAMS are the more economical.

aximum Safe Loads for Steel Beams. All loaded beams are, in general, ject to three kinds of stresses. The most destructive are generally those e to the BENDING MOMENTS, and have already been considered. The second s are those which tend to SHEAR a beam, or to make one part slide on other vertically. (See paragraph on Shearing-Stresses in Steel Beams and ders, page 567.) These stresses, however, seldom need to be considered pt in the case of riveted girders and short beams with very thick webs. e third kind of stress is that which tends to cause the web of a beam to KLE; and in a steel beam over a span very short in proportion to the th of the beam, the resistance of the web to buckling generally determines maximum load that the beam, without stiffeners on the web, will support. e also, pages 182, 183 and 567.)

e Loads for Steel Beams.* To save time in calculating, tables of safe s for structural and supplementary beams and channels used as beams r conditions of transverse loading, have been prepared, which give the UNI-LY DISTRIBUTED SAFE LOADS in thousands of pounds for spans customary

* Part of the matter of the following paragraphs relating to steel I beams has been ed by permission, from the Pocket Companion, Carnegie Steel Company, Pitts-, Pa.

in building-construction. They are based upon an extreme FIBER-STRESS 16 000 lb per sq in on the fibers farthest from the neutral surface of the be

The Tables of Safe Loads for Angles and Tees, pages 586 to 591, the values at the same fiber-stress on spans of one foot, from which the safe for any span-length may be obtained by direct division, and also the values those spans at which the allowed safe load will produce a deflection of ⅟₃₆₀ the span-length. The loads in all cases include the weight of the beam, w should be deducted in order to arrive at the net load which the beam will supp For several concentrated loads or for a combination of distributed and con trated loads it will be necessary to use the methods previously explained u Case VIII, page 563.

Use of Tables for Concentrated Loads. To use any of the follo tables for CONCENTRATED LOADS, find the equivalent distributed load by m plying the concentrated load by the factor given in Table IV, page 632, then use the beam having a safe load equal to the load thus found.

In addition to the conversion-factors in that table the following, also, wi found convenient:

For two equal loads applied at one-third the span from each end, multiply load by 2⅔.

For two equal loads applied at one-fourth the span from each end mul one load by 2.

For a beam fixed at one end, and loaded at the other, multiply by 8.

For a beam fixed at one end, and uniformly loaded over the entire le multiply by 4.

Unusual Conditions of Loading of Beams.* It is assumed in all that the loads are applied normal to the axis 1–1 as shown in the tables o properties of sections in Chapter X, and that the beam deflects vertically i PLANE OF BENDING ONLY. If the conditions of loading involve the intr tion of forces outside this plane of loading, the allowable safe loads mu determined from the general theory of flexure in accordance with the mo application of the load and its character. This applies particularly to un METRICAL SECTIONS, such as angles, which should be used under those c tions of loading where the section can deflect vertically only, being rigid cured against LATERAL DEFLECTION or twisting throughout the entire In all such cases of eccentric loading, the actual safe loads would be conside lower than the tabulated safe loads, which have been based upon the favorable conditions of loading.

Vertical Deflection of Steel Beams.* In the case of beams intend carry plastered ceilings, experience indicates that the VERTICAL DEFLEC to avoid cracking the plaster, should be limited to not more than ⅟₃₆₀ spain-length. This SPAN-LIMIT for steel beams is approximately, in feet, the depth in inches and is indicated in the tables by the lower, broken, zontal lines. Beams intended for such purposes should not be used for g spans unless the allowable tabular safe load exceeds the actual load to b ported. As the dead load of a floor is supported by the floor-beams befo plaster is applied, only the deflection due to the live load really needs considered. The vertical deflection of beams is explained in Chapter XV

Lateral Deflection of Steel Beams.* The tabular safe loads are upon the assumption that the compression-flanges of the various sectio

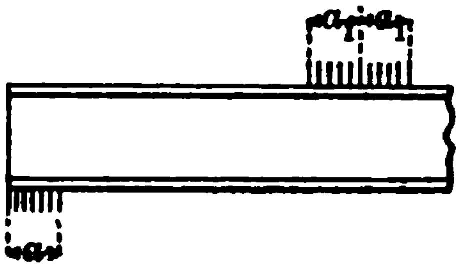
beams with unsupported webs, and from these experiments the following
mulas * have been deduced:



Safe end-reaction $R = S_b \times t\left(a + \frac{d}{4}\right)$

Safe interior load $P = 2\,S_b \times t\left(a_1 + \frac{d}{4}\right)$

In these formulas, R is the end-reaction, P the concentrated load, t the
thickness, d the depth of the beam, a_1 half the distance over which the con
trated load is applied and a the whole distance over which the end-reacti
applied; while S_b is the SAFE RESISTANCE OF THE WEB TO BUCKLING, in po
per square inch, by the straight-line formula

$$S_b = 19\,000 - 100\,d/2\,r$$

$d/2 = l$ in the column-formula †. The first formula is general and appli
any condition of loading. The second formula covers the case of a single
concentrated at the middle of a span; it can be extended to cover a syste
concentrated loads provided the sum of the distances a_1 is not less than a.

Tables II ‡ and III ‡ give for beams and channels with unsupp
webs:

* These formulas, in order to satisfy the first condition, are used in the Pocket
panion, 1915 Edition, Carnegie Steel Company, Pittsburgh, Pa.

† This is the column-formula used by the American Bridge Company and in Carn
Pocket Companion, S being the allowable COMPRESSIVE UNIT STRESS in pounds
square inch within the usual limits of l/r. See Formula (13), page 481.

‡ In regard to the shearing of steel beams, allowable web-shears, etc., the valu
example (see Example 15, this chapter, and on pages 182 and 183 of Chapter
42 000 lb per sq in for a 12-in, 31.8-lb I beam, given in Table II, page 575, takes
Carnegie's Pocket Companion, is based on the allowed direct shear without includi
condition of web-crippling. That is, the 42 000 lb is determined by taking the
the web, 0.35 × 12 = 4.2 sq in and multiplying it by 10 000 lb per sq in, which
value there used for the safe unit shearing-stress.

The beam is therefore calculated as being good for 42 000 lb SHEAR, but it is nec
to make a further investigation to ascertain whether the stresses due to shear will
the web of the beam to buckle. As stated in the paragraph on page 567, on the Bu
Values of Beam-Webs there are two conditions of web-buckling or web-crippling.

In the case of a plate girder the end-stiffeners provide for the first condition, a
intermediate stiffeners for the second condition. The web itself may then be coun
for its full shearing value. In the case of beams, however, it is not generally econ
to use stiffeners, so that the web alone must meet every condition.

The Carnegie Pocket Companion gives a formula, reproduced in the preceding
graph, and gives the derived lengths of bearings in Tables II and III, to satisfy t
condition. Some of the formulas used in the manufacturers' handbooks, for ma
safe shear based on web-buckling for the second condition, are as follows:

Passaic Steel Company, $V = \dfrac{10\,000\,dt}{1 + \dfrac{h^2}{3\,000\,t^2}}$

Cambria Steel Company, $V = \dfrac{12\,000\,dt}{1 + \dfrac{h^2}{1\,500\,t^2}}$

Bethlehem Steel Company, $V = \dfrac{12\,000\,dt}{1 + \dfrac{h^2}{3\,000\,t^2}}$

(1) "The allowed WEB-RESISTANCE S_b, in pounds per square inch, computed from this compression-formula. (See, also, page 183.)

(2) "The distance a, or the distance over which the end-reaction must be distributed when the shearing-stress V in the web is the maximum allowable stress of 10 000 lb per sq in.

(3) "The allowable END-REACTION R, when a is taken at 3½ in, which is the usual length of beam actually resting on the 4-in angles ordinarily used in building-construction for beam-seats.

(4) "The allowable SHEAR V, on the gross area of the cross-section of the beam or channel-webs, at 10 000 lb per sq in."

In regard to the second condition of WEB-BUCKLING, the MAXIMUM ALLOWABLE SHEAR may be calculated by the formula,

$$V = \frac{12\,000\,dt}{1 + \dfrac{h^2}{1\,500\,t^2}}$$

in which V = the maximum safe web-shear in pounds; d = the depth of the beam; t = the thickness of the web; and h = the height between the flange-fillets. (See Example 15, this chapter and also example on pages 182 and 183.)

"In addition to these data which have to do with the MAXIMUM LOADS on beams and channels as computed from the WEB-RESISTANCE, Tables II and III give, also, the MAXIMUM BENDING MOMENTS in foot-pounds, obtained by the multiplication of the SECTION-MODULUS of each section by the allowed FIBER-STRESS 16 000 lb per sq in and the division of the product by 12 in order to reduce it to a foot-pound basis. These maximum bending moments may be used on occasion instead of the table of properties to ascertain the proper size of a section to be used in any particular instance."

... of which V = the maximum safe web-shear in pounds; d = the depth of the beam; t = the thickness of web; and h = the distance between the flange-fillets.

It is to be noted that the length of the element in compression on the 45° line is $h\sqrt{2}$, and that the square of this length is $2h^2$. It is this value, $2h^2$, that is substituted for l^2 in the column-formula used by the Cambria Steel Company in deducing its formula for shear based on web-buckling. The tensile stress, however, tends to keep the compressive ... from buckling the web, and for this reason the Passaic and Bethlehem engineers ... the more liberal value of $3\,000\,t^2$ instead of $1\,500\,t^2$. The Passaic Steel Company, however, used the more conservative unit value of 10 000 lb, reduced, instead of the ... lb used by the others. The Passaic and Cambria formulas give about the same ..., a 12-in, 31½-lb I beam by the former having a safe shear of 33 352 lb and by the ..., 33 188 lb.

The Passaic Steel Company is no longer in existence and their handbook is out of print. The Bethlehem Steel Company's handbook has tables for Bethlehem shapes only. If, in any case, no table of maximum shears of beams, based on web-crippling, is at hand, it is suggested that the values may be determined from the formula,

$$V = \frac{12\,000\,dt}{1 + \dfrac{h^2}{1\,500\,t^2}}$$

in which, as before, V = the maximum safe web-shear in pounds; d = the depth of the beam; t = the thickness of the web; and h = the distance between the flange-fillets. For the beam mentioned and used in Example 15, page 571, in this chapter and in the example on pages 182 and 183, d = 12 in, t = 0.35 in, h = 9.762 in, t^2 = 0.1225, ... 95.296644 and V = 33 188 lb. This formula is recommended as being the most conservative, although there is not a great difference in the results, and the formula of the former Passaic Steel Company is retained elsewhere in Kidder's Pocket-Book. See, for example, page 686 and Table III of Chapter XX. Editor-in-chief.

Table VII is a table computed by Mr. Kidder, giving the strength small rectangular steel channels or grooved steel. These are often used supporting metal lath in suspended ceilings, and the table will be found us in determining the size to use for any given span and spacing.

4. Tables of Safe Loads for Steel Beams and Girders. Examp

Example 9. Direct Bending from a Uniformly Distributed Load. As illustration of the use of these tables let it be required to determine the pr size and weight of an I beam to carry safely a uniformly distributed loa 34 000 lb over a span of 20 ft, the weight of the beam not being included.

Solution. From Table IV, page 579, a 15-in 50-lb beam will carry 34 40 The weight of this beam is 50 lb × 20 ft = 1 000 lb, making a total load t supported of 35 000 lb. This is so little in excess of the safe load that the e need not be considered. Had the difference been more, however, the heavier beam should be used.

Example 10. Direct Bending from a Concentrated Load. To illustrate use of the tables to determine the size and weight of beams required to concentrated loads, Examples 10 and 11 are given. What I beam, 15 ft in s will safely support 8 000 lb, concentrated at a point 5 ft from the left sup

Solution. The distance 5 ft is one-third of the span, and the conver factor for this (Table IV, page 632) is 1.78. The equivalent uniformly tributed load, therefore, is 8 000 × 1.78 = 14 240 lb, and from Table IV, 581, a 9-in 25-lb I beam will carry 14 500 lb for a span of 15 ft, and will answer the purpose.

Example 11. Direct Bending from Two Equal Concentrated Loads. I beam, 15 ft in span, will safely support two equal concentrated loads of lb each, applied 5 ft from each end?

Solution. The distance 5 ft is one-third the span, but the multiplier in case is 2⅔ (page 566). Hence, the equivalent uniformly distributed lo 6 000 × 2⅔ = 16 000 lb and the beam required (Table IV, page 580) is a 25.4-lb I beam which will carry 17 400 lb. The same result is obtain using Formula (11)′, page 562. This formula is, $I/c = 12\,Pm/S$. Substit $I/c = 12 \times 6\,000 \times 5/16\,000 = 22.5$. The nearest section-modulus to this is that of a 10-in 25.4-lb I beam.

Example 12. Maximum Bending Moment from a Distributed Load Ove of the Span. The beam in Example 5, Case V, page 561, has a maximum ing moment of 26 666 ft-lb. What beam is required?

Solution. The nearest bending moment to this in the first column of II, page 575, is 27 240 ft-lb, which corresponds to a 9-in 25-lb I beam.

Example 13. Allowable Web-Shear.* The maximum shear in the be Example 12 is just at the right of the left reaction or bearing, and equals lb. Is the beam safe for shear?

Solution. From Table II, page 575, in the column for V, the allowabl shear for a 9-in 25-lb beam is 36 540 lb. Hence, the beam is safe if web-bu is not taken into account.

Example 14. Shear.* It is required to determine the maximum load a 9-in 25-lb I beam can support without exceeding the safe web-resista the section.

* See paragraphs and foot-note relating to buckling of beam-webs, pages 567 t

Solution. From Table IV, page 581, the maximum load for this beam, given in small figures above the heavy, horizontal lines, is 73 100 lb.

Example 15. Safe Buckling Resistance. See, also, paragraphs and foot-note relating to buckling of beam-webs on pages 567 to 569 and also example on pages 182 and 183. According to Table II, page 575, the allowable web-shear for a 12-in, 31.8-lb I beam is 42 000 lb. Will this shear cause the web of the beam to buckle?

Solution. The web-shear is determined by multiplying the area of the web, that is, 0.35 in × 12 in = 4.2 sq in, by 10 000 lb per sq in, the safe unit shearing-stress. The maximum shear which will not cause the web to fail by buckling may be found by the formula given on page 569 for the second condition of web-buckling.

$$V = \frac{12\,000\,dt}{1 + \dfrac{h^2}{1\,500\,t^2}}$$

From the dimensions of structural beams (see Carnegie's Pocket Companion, Beams, Profiles, Weights, etc.) the thickness t of the web of a 12-in, 31.8-lb beam is 0.35 in, the depth of the beam is d = 12 in and h, the distance between flange-fillets, is 9.762 in. Substituting these values in the formula,

$$V = \frac{12\,000 \times 12 \times 0.35}{1 + \dfrac{9.762^2}{1\,500 \times 0.35^2}} = \frac{50\,400}{1 + \dfrac{95.296644}{1\,500 \times 0.1225}} = \frac{50\,400}{1 + \dfrac{95.296644}{183.75}} = \frac{50\,400}{\dfrac{279.046644}{183.75}}$$

$$= \frac{50\,400 \times 183.75}{279.046644} = \frac{9\,261\,000}{279.046644} = 33\,188, \text{ or about } 33\,190 \text{ lb}$$

As this is less than the allowable web-shear of 42 000 lb given in the tables, account is to be taken of the web-buckling from the second condition mentioned in the preceding pages, a larger or heavier beam should be used or the loads reduced, so that the maximum shear will not exceed 33 190 lb. (For determining conditions for web-buckling of steel beams in grillages, based on direct compression, see page 183.)

Example 16. Safe End-Reactions for Web-Buckling. In Example 8, page 5, the two 24-in 90-lb I beams carry 170 000 lb + (4 000 lb, the weight of the beams) = 174 000, lb or 87 000 lb for each beam. Assuming that they rest on 4-in brackets riveted to columns at each end of the span, are the end-reactions excessive?

Solution. Since the loading is symmetrical, each reaction for each beam is one-half the total load on each beam, or 43 500 lb. From the last column in Table II, page 574, the maximum end-reaction R, for a 24-in 90-lb beam, is 310 lb. Hence, the beam is safe as far as the compression from the end-reactions is concerned.

Strut-Beams. It is not considered good construction to subject a strut to a transverse loading, causing a certain amount of flexure in it and thus adding to the compressive stress. Conditions often exist, however, where practical considerations make it desirable to use a strut as a beam, also, as in the top chord or in the principals of a truss. To determine the size of a member in a case of this kind the following method should be used:

(1) Find the section-modulus I/c, for the member for the transverse load by formulas (2)′ to (11)′, using 12 000 lb per sq in as the value of S, and find the area of the cross-section of a steel shape corresponding to the value of I/c thus found. See note at end of Example 17, relating to value of S.

(2) Find the section-area required to resist the compressive stress, by divic that stress by the value opposite l/r in column VIII of Table XI, page 49:

(3) Add together the two areas and use for the required member a piec pieces of material having a section-area next larger than the total area fo

Example 17. Strut-Beam. Combined Bending and Compression. principal rafter in a truss, 8 ft 6 in long between joints, supports the end purlin at the middle of the span. The weight from the purlin is 2 800 lb and compressive stress in the rafter 30 000 lb. It is proposed to use a pair of an for the rafter, set with the long legs vertical and ½ in apart. What are dimensions of the angles, the strut being braced laterally?

Solution. (1) By Formula (8)′, $I/c = 3 \times 2\,800 \times 8.5/12\,000 = 5.95$ for pair of angles, or 2.98 for each angle. (See note at end of this example.) F Table XI, page 363, the nearest value to this with reference to the axis 1- 3.0, the section-modulus for a 5 by 3½ by ½-in angle. The section-area of angle is 4 sq in and of two angles, 8 sq in.

(2) From Table XVI, page 371, the least r for a pair of 5 by 3½ by angles, which would be about the axis 1–1, since the strut is braced later is about 1.58 (between 1.53 and 1.61). Then the slenderness-ratio $l/r =$ 6 in/1.58 in = 102 in/1.58 in = 64.5. From column VIII, Table XI, 493, $S = 9\,250$ lb per sq in. Hence, 30 000 lb/9 250 lb per sq in = 3.24 sq approximately.

(3) The section-area required, therefore, is 8 + 3.24 = 11.24 sq in, which, Table XI, page 363, is about equivalent to that of two 5 by 4 by 1½ angles. As the section-area in both calculations exceeds that actually requ no allowance for the weight of the angles need be made.

Note. Because of the increase in the tendency of the strut to deflect, ca by the combined stresses of flexure and compression, lower values of S are than in the cases of simple flexure, or of simple compression.

Tie-Beams. Steel beams subject to combined tensile and transverse str should be calculated in a way similar to that explained above for strut-be The section necessary to resist the transverse stress should be found first, the section-area necessary to resist the tensile stress, and the two added toge

Example 18. Tie-Beam. Combined Bending and Tension. One span tie-beam, 10 ft between joints, supports a load of 6 000 lb at the middle, a the same time is under a tensile stress of 84 000 lb. It is proposed to use steel channels for the tie-beam. What size and weight are required fo channels?

Solution. A load of 6 000 lb applied at the middle of a beam has the effect as a load of 12 000 lb uniformly distributed, or 6 000 lb for each cha From Table V, page 584, a 7-in, 9.8-lb channel will be required, its sec area (Table VIII, page 359) being 2.85 sq in. The additional area requir resist the tensile stress is 84 000 lb/16 000 lb per sq in = 5.25 sq in, or 2.6 each channel. The total area for each channel, therefore, should be 2.85 - = 5.48 sq in. A 7-in, 19.75-lb channel has a section-area of 5.79 sq in an 8-in, 18.75-lb channel has a section-area of 5.49 sq in. Either one w sufficient, but the 8-in channel will probably be more economical, as it w 1 lb per ft less.

Example 19. Channel, Set Flatwise. What is the size of the channe flatwise, required to support a uniformly distributed load of 180 lb per ft a span of 10 ft, or 120 in?

Solution. $W = 180 \times 10 = 1\,800$ lb. From Case V, page 326, $M_{max} = W$ $1\,800 \times 120/8 = 27\,000$ in-lb. From Formula (3)′, page 557, $I/c = M$

.000/16 000 = 1.7. From Table VIII, page 359, the I/c about the axis 2-2 ...responding to this is that of a 12-in, 20.7-lb channel.

...ample 20. Rectangular Steel Bar with Long Side Vertical. In a suspended, ...stered ceiling it is proposed to use 2 by ⅝-in steel bars, 4 ft or 48 in long, to ...ry the plaster. What is the safe load each bar will support, if set with the ...g side vertical?

...lution. From Table I, page 346, the I for a 2 by ⅝-in bar is 0.250. c = ...-half the depth = 1 in. $I/c = 0.250/1 = 0.250$. Also, from Formula (2)', ...e 557, $M_{max} = SI/c$. Substituting, $M_{max} = 16\,000 \times 0.250 = 4\,000$ in-lb ...t, from Case V, page 326, $M_{max} = Wl/8$, and hence, $4\,000 = W \times 48/8 =$ ...W, and $W = 4\,000/6 = 666$ lb.

Oblique Loading of I Beams and Channels *

Oblique Loading of Purlins on Sloping Roofs. (See, also pages 593, ...9 and 1170.) In Tables II to V it is assumed that I beams and channels ...set with webs vertical and carry vertical loads. This is not the case when ...d as PURLINS ON SLOPING ROOFS. There are then fiber-stresses due to the ...ponents of the bending moment both at right-angles and parallel to the ...e of the roof. The resultant fiber-stress may be calculated from the ...ation on page 1170. This equation is used in determining the values ...n in Table I A. It may be noted that the second term causes the fiber-...s to increase rapidly with the slope of the roof. If purlins were propor-...ed according to the equation given or from the Table I A, they would often ...uch larger than those commonly used. For small slopes the second term ...the equation may be reduced or eliminated by the stiffness of the roof-...ing, and for other slopes by connecting the purlins with SAG-RODS running ...the sloping sides of the roof to an unyielding connection at the peak.

Loads above the upper heavy lines will cause maximum allowable shears in [we]bs. See, also, paragraphs in text and foot-note with same, page 567, relating to [we]b-buckling in beams

[Lo]ads below the lower broken lines will cause excessive deflections

Loads above the upper heavy lines will cause maximum allowable shea webs. See, also, paragraphs in text and foot-note with same, page 567, rel to web-buckling in beams.

Loads below the lower broken lines will cause excessive deflections

* From Pocket Companion, Carnegie Steel Company, Pittsburgh, Pa.

Table IV * (Continued). Safe Uniform Loads in Units of 1 000 Pounds for Steel I Beams

Maximum bending stress 16 000 lb per sq in. Beams secured against yielding sidewise

Bethlehem I Beams.* BETHLEHEM I BEAMS from 8 to 24 in in depth clusive, have the same strength, or section-modulus, as STANDARD BEAMS of same depth. Bethlehem beams, due to the proportions of the sections, w generally 10% less than standard beams of the same depth and strength. example (Table VI, page 357), a Bethlehem 15-in I beam, weighing 54 lb ft, has a section-modulus of 81.3. The corresponding standard section (T IV, page 354) is a 15-in I beam weighing 60.8 lb per ft, with a section-mod of 81.2. Therefore, for equal strength, the Bethlehem beam weighs 6.8 lb p less than the standard beam, or saving over 10% in weight. Similar c parisons with other sizes of the standard beams previously rolled by the r of this country show that the Bethlehem I beams afford an equal carr capacity, but with practically 10% less weight of metal.

Thickness of Webs and Flanges. It is claimed that the WEBS of stan beams are much thicker than required for a scientifically proportioned sec It is impossible to reduce the WEB-THICKNESS in the ordinary mill, but the Grey Mill webs of the desired thickness can be produced. By addin the FLANGES part of the metal thus saved, the strength of the beam is m tained, thereby affording a lighter section of the same strength. The v FLANGES give increased lateral stiffness, which commends the use of such b in many cases, where the NARROW FLANGES and lack of sufficient lateral rig prevent the use of ordinary standard beams.

Depth and Weight of Bethlehem Beams. Formerly the heaviest b rolled in this country were 24 in deep, weighed 115 lb per ft, and had a sec modulus of 246.3. Whenever greater strength was required, a riveted g was necessary. Bethlehem beams are rolled to a maximum depth of 3 weigh 200 lb per ft, and have a section-modulus of 610, or two and one times the strength of the largest beam previously rolled. The opportunit using ROLLED BEAMS instead of BUILT-UP RIVETED GIRDERS is, therefore, gr increased. These rolled beams and girders afford a saving in WEIGHT OF M and also a large economy in COST OF FABRICATION, as they do not requir punching, assembling and riveting necessary for building a riveted girder

Bethlehem Girder Beams.* BETHLEHEM GIRDER BEAMS, from 8 to in depth, inclusive, have a strength, or section-modulus, equal to that of minimum-weight STANDARD I BEAMS of the same depth. The girder b however, weighs generally 12½% less than the combined weight of the standard beams, not considering the saving in weight of separators neede assembling the standard beams into a girder. For example, a Bethlehem girder beam, weighing 73 lb per ft has a section-modulus of 117.8 (Table page 358). Two standard 15-in I beams, each weighing 42 lb per ft, together a like section-modulus of 117.8 (Table IV, page 354). Thus, for depth and strength, the girder beam weighs 11 lb per ft less than the standard beams. This is a saving of 13% in weight, not including separa which would add at least 2½ lb per ft more to the weight of the assem girder. In this case a total saving of 16% in weight is afforded by the Be hem girder beam, besides the saving in the cost of assembling the stan beams into a girder.

Safe Uniformly Distributed Loads for Bethlehem I Beams and Gi Beams. Tables XII * and XIII,* pages 594 to 602, give the SAFE UNIFO DISTRIBUTED LOADS in tons of 2 000 lb, on Bethlehem girder beams and I b for a maximum fiber-stress of 16 000 lb per sq in. The tabular loads in

* Adapted by permission from the Catalogue of Bethlehem Structural Shapes, B hem Steel Company, South Bethlehem, Pa.

e weight of the beam, which must be deducted to obtain the net load a beam ill support. Safe loads for INTERMEDIATE OR HEAVIER WEIGHTS of beams can obtained from the separate COLUMN OF CORRECTIONS, given for each size his last column of the table states the increase in safe load for each pound increase in weight per foot of beam. If the load is CONCENTRATED AT THE DDLE OF THE SPAN, the safe load is one-half the safe uniformly distributed d for the same span. The SAFE LOADS ON SHORT SPANS may be limited by e shearing strength of the web, instead of by the maximum fiber-stress lowed in the flanges. This limit is indicated in the tables by the heavy hori- ntal lines. The loads given above these lines are greater than the SAFE CRIP- LING OF BUCKLING STRENGTH OF THE WEB, and must not be used unless the ebs are stiffened.* In such cases it will generally be advisable to select a avier beam with a thicker web. To use these tables for other spans, or for her distribution of the loading, see explanation, page 566. To use these tables r beams YIELDING LATERALLY, see Lateral Deflection, pages 566 and 670.

blique Loading of Angles Used as Beams †

Oblique Loading of Purlins on oping Roofs. (See, also, pages 3, 1169 and 1170.) The preceding bles VIII, IX and X for safe loads angles are based on the neutral is being parallel to one of the legs. hen this is not the case, as in roof- rlins (Fig. 10), the strength of a an angle may be found by taking section-modulus from Table XI A d using the fundamental formula r flexure (page 557). It should be ted that purlins set as at (*a*) are onger than (*b*), Fig. 9A.

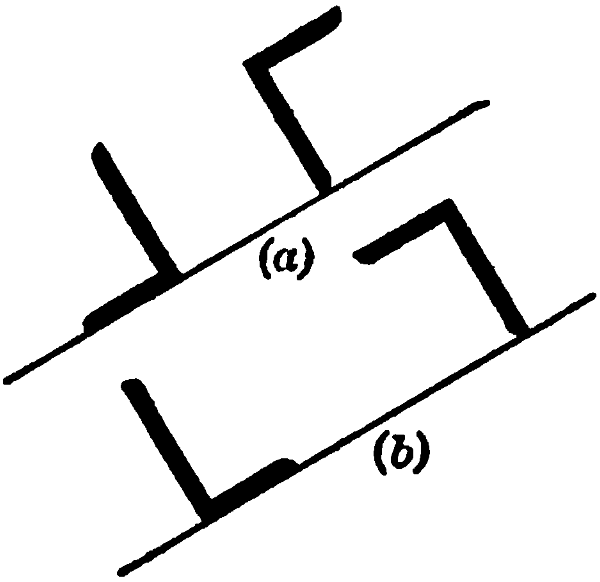

Fig. 9A. Strong and Weak Setting of Angle-Purlins on Sloping Roofs

ble XI A. Section-Moduli of Angle-Purlins Set at Right-Angles to Rafters, as in (a) Fig. 9A, and Free to Move in Any Direction. Loading Vertical.

Purlin	Slope of roof in inches per foot						
	0	1	2	4	5	6	8
× 2 × 1/4 angle	0.18	0.19	0.20	0.22	0.24	0.26	0.31
½ × 2 × 1/4 angle	0.30	0.31	0.33	0.38	0.41	0.44	0.49
½ × 2½ × 1/4 angle	0.31	0.32	0.33	0.37	0.39	0.42	0.48
½ × 2½ × 3/8 angle	0.42	0.44	0.46	0.52	0.55	0.60	0.68

Safe loads given include weight of beam. Maximum fiber-stress, 16 000 lb per sq in

Loads given above the heavy lines are greater than safe loads for web-crippling. See paragraphs and accompanying foot-note, page 567, relating to web-buckling of beams

Safe loads given below the lower, broken line cause deflections exceeding 1/360 of the span

The section-numbers are given for convenience in identification and ordering

Safe loads given include weight of beam. Maximum fiber-stress, 16 000 lb [per] sq in

Safe loads given below the broken lines cause deflections exceeding 1/360 of span

The section-numbers are given for convenience in identification and orderi[ng]

...ed Single-Beam and Double-Beam Girders.* Where a SINGLE ...LE-BEAM is insufficient to carry a load, the required capacity may be secured ...brication in various ways. TWO BEAMS can be used, connected by bolts ...separators. The total strength of these is twice that of the SINGLE BEAM ...he same depth and weight. Care should be taken, however, to see that ...loads are apportioned to them equally, and where it is necessary for the ...s to act as a unit, the separators should consist of plates and angles and not ...ade of cast iron. If the loading is not uniformly distributed over the two ...s, the strength of each must be computed separately. The use of a SINGLE-...M GIRDER with plates at top and bottom to sustain a given load is often more ...omical in material than the use of TWO BEAMS connected by bolts and ...rators. The beam girders in Table XIV, pages 605–6, have about twice ...carrying capacity of the single beams of which they are built.

...ables XIV and XV give the SAFE LOADS for the SINGLE AND DOUBLE-BEAM ...ERS commonly used. The values given in the tables are founded upon ...moments of inertia of the various sections, deductions being made for the ...t-holes in both flanges. In Table XIV, taken by permission from Carnegie's ...ket Companion, the safe loads are based upon a fiber-stress for flange-bend... of 16 000 lb per sq in, and in Table XV, retained from the former edition of ...der's Pocket-Book, upon a fiber-stress of 13 000 lb per sq in. For other fiber-...ses, as 14 000 or 15 000 lb per sq in, the safe loads in Tables XIV or XV ...y be decreased or increased by PROPORTION as the LOADS vary as the FIBER-...ESSES.†

* For tables of riveted plate girders, see Chapter XX.

† The editors decided to retain Table XV for the safe uniformly distributed loads for ...ed steel-beam box girders, based upon a bending fiber-stress of 13 000 lb per sq in. ...se this table for fiber-stresses of 14 000, 15 000 or 16 000 lb per sq in, divide the ...ar loads by 13 and multiply the quotients by 14, 15 or 16, respectively, for the safe ...s at the required fiber-stress. In regard to Table XV, Mr. Kidder said, in the ...ding editions of this pocket-book, "in order to amply compensate for the deteriora-... of the metal around the rivet-holes from punching, and also because these girders ...re often used to support permanent loads, such as brick or stone walls, the maximum ...-stress [for riveted double-beam girders] was limited to 13 000 lb per sq in, although ...but right to state that most of the latest handbooks of the steel-manufacturers give ...s of safe loads for such girders based upon a fiber-stress of 15 000 lb per sq in. ...author advises that for loads of masonry, which usually come very close to the ...ated loads, and which are constantly applied, the girders be not loaded beyond the ...s given in the following tables (that is, based upon 13 000 lb per sq in), while for ...ary floor-loads, which seldom reach the estimated loads, an addition of ⅙th may be ...d to the values given in the tables."

...ders fabricated of single steel I beams and plates riveted to the upper and lower ..., as shown in Table XIV, are not often used to support masonry walls, because of ...relatively narrow flange-width and lack of lateral stiffness. In case they are used ...port masonry walls and are not thoroughly braced laterally, it is recommended that ...afe loads be reduced as explained, from those given in Table XIV, to agree with ...r-stress of 13 000 or 14 000 lb per sq in, according to the span, bracing, character ...ding, etc. It is recommended, also, that for girders fabricated of two steel I beams ...plates riveted to the flanges, as shown in Table XV, and carrying masonry walls, the ...loads, given in this table and computed for a fiber-stress of 13 000 lb per sq in, be used, ...increased, that the fiber-stress be taken not greater than 14 000 lb per sq in.

...ent handbooks have contained tables of safe uniformly distributed loads for fabri-...d steel girders computed from safe unit fiber-stresses, in pounds per square inch, ...flange-bending as follows. For RIVETED SINGLE-BEAM GIRDERS: Carnegie Steel ...any, 1903 Edition, no tables; Carnegie, 1915 Edition, 16 000, based upon the ...n-modulus of the gross area of the cross-section; Cambria Steel Company, 1912 ...ion, no tables; (former) Passaic Steel Company, 1903 Edition, no tables; Kidder's ...ket-Book, previous editions, no tables. For RIVETED DOUBLE-BEAM GIRDERS: Car-

Example 21. A 13-in brick wall, 15 ft high, is to be built over an openin
24 ft. What is the size of the double-beam girder required?

Solution. Assuming 25 ft as the distance, center to center of bearings a d
lb per cu ft as the weight of brickwork, the weight of the wall is 25 × 15 ×
45 375 lb, or about 22.68 tons. From Table XV, page 610, a girder compos
two 12-in steel beams, each weighing 31.5 lb per ft, and two 14 by ½-in fl
plates will carry safely, for a span of 25 ft, a uniformly distributed load of
tons, including its own weight. Deducting the latter, 1.42 tons, given i
next column, the result is 21.81 tons for the safe net load, which is 0.87 to
than required. From the following column of the table it is seen that b
creasing the thickness of the flange-plates 1/16 in it is safe to add 1.52 tons t
allowable load. This will more than make up the difference. Hence th
quired DOUBLE-BEAM GIRDER will be composed of two 12-in 31.5-lb b
and two 14 by 9/16-in steel flange-plates.

A SINGLE-BEAM GIRDER (according to Table XIV, page 606), compos
one 15-in 42-lb I beam and two 8 by ½-in flange-plates will carry, at 1
lb per sq ft, 49 000 lb over a span of 25 ft, and as it is lighter, weighin
69.2 lb per ft to the others 113.6 lb, it would be more economical.
DOUBLE-BEAM GIRDER is, however, more suitable in this particular case,
13-in wall should have a wider bearing than 8 in, and, also, the safe load s
be decreased from the tabular load to correspond to a fiber-stress of 13 c
14 000 lb per sq in because of the nature of the loading, the long span,
or, what amounts to the same thing, the strength of the girder shou
increased to correspond to the decreased fiber-stress. (See foot-note, page
A 49 000-lb load at 16 000 lb per sq in fiber-stress corresponds to a 49
16/13 = 60 307-lb load at 13 000 fiber-stress, as far as selecting a correspo
girder from table is concerned. A SINGLE-BEAM GIRDER (Table XIV)
posed of one 15-in 60-lb I beam and two 9 by ⅝-in flange-plates will
68 000 lb and weighs only 98.3 lb per ft. Therefore, as far as strength i
cerned, to suit the conditions of loading, this would be the proper SINGLE-
GIRDER to use, and it would also be cheaper than the DOUBLE-BEAM G
determined by Table XV; but the width of bearing for the 13-in wall i
only 9 in compared to 14 in with the DOUBLE-BEAM GIRDER.

negie, 1903, 15 000, 13/16-in rivet-holes deducted; Carnegie, 1915, no tables; Ca

e above values based on a maximum fiber-stress of 13 000 lb per sq in, rivet-hole th flanges deducted. See paragraph on Riveted Single-Beam and Double-Bean page 603, and the foot-note for same regarding fiber-stresses. Weights of girder ond to lengths, center to center of bearings.

Beams Supporting Brick Walls. In calculating the size of a girder to s port a brick wall, the structure of the wall should be carefully considered. the wall is without openings and does not support floor-beams, only that p of the wall included within the dotted lines, Fig. 10, need be considered as b supported by the girder. The beams in that case, however, should be made very STIFF, so as to have little DEFLECTION. If there are several openings above the girder, and especially if there is a pier over the middle part of it, as shown in Fig. 11, then the manner in which the loading is distributed should be carefully considered. In a case of this kind, only the dead weight included between the dotted lines AA and BB should be considered

Fig. 10. Triangular Loading of Beams under Brick Walls

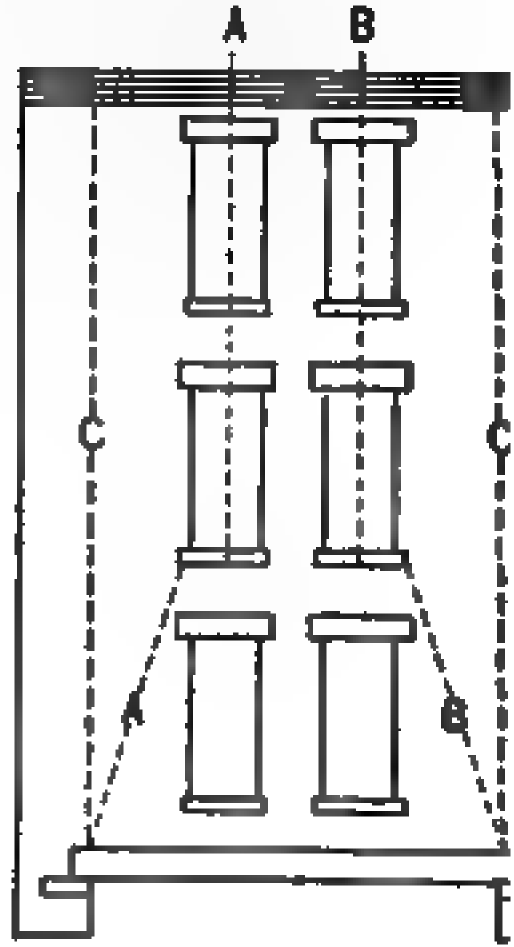

Fig. 11. Loading of Beams u Walls with Openings

as coming upon the girder, and proper allowance made for the CONCENTRA of the greater part of the load at or near the middle. If, however, the b windows are two-thirds their total width, or more, above the girder, th is more reasonable to suppose that the wall included between the line rests upon the girder, and also to consider that this load is UNIFORMLY TRIBUTED over it. When beams extend under the entire length of a which is more than 16 or 18 ft long, the weight of the entire wall rather the weight of a triangular part of it should be taken as coming upon beams; for, if they should bend, the wall would settle, and might push the supports and cause the whole structure to fall. (See, also, page 318.

5. Framing and Connecting Steel Beams and Girders

Standard Separators. When beams are used to support walls, or as g to carry floor-beams, they are often placed side by side; and should in cases be connected by means of BOLTS and cast-iron SEPARATORS f closely between the flanges of the beams. The office of these separators i measure, to hold in position the compression-flanges of the beams by preve SIDE DEFLECTION or BUCKLING, and also to unite the beams so as to them to act in unison as regards VERTICAL DEFLECTION. Separators s be provided at the supports, at points where heavy concentrated loa imposed, and at regular intervals of from 5 to 6 ft between. The ill tions, dimensions, etc., given in Table XVI, are for the STANDARD SEPAR in common use.

¾" cored hole

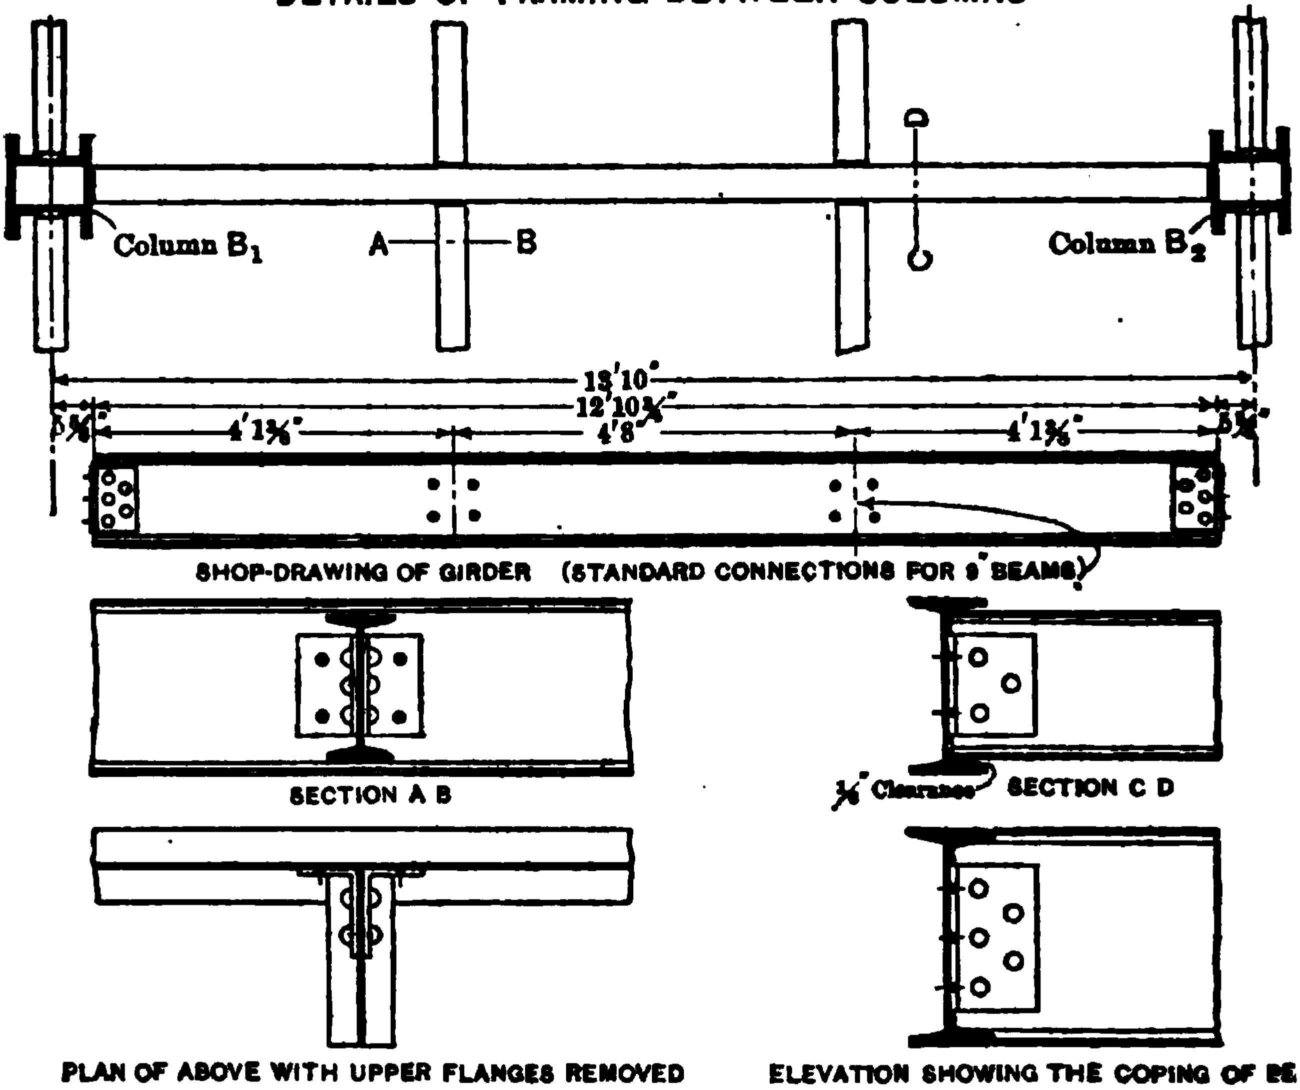
For 5-in, 4-in and 3-in beams, use 1-in gas-pipes, 3¼, 3 and 2¾-in long, respectively

* From Pocket Companion, Carnegie Steel Company, Pittsburgh, Pa.

Gas-Pipe Separators. Separators formed of pieces of GAS-PIPE, cut to desired lengths and slipped over the bolts are often used by contractors. (bottom of Table XVI.) Such separators permit the beams to act independe of each other, and should not be used in any place where one beam is liabl receive a greater load than the other; and as this condition exists in alm every case where two or more beams are used together, it follows that "c iron separators, made to fit the space between the beams," should be speci in almost every instance. As noted in Table XVI, gas-pipe may sometime used for 5, 4 and 3-in beams. Separators with two bolts should be used beams 12 in or more in depth. For 12-in beams one bolt is sometimes used w the load is light; for beams under 12 in in depth one bolt is sufficient.

FRAMING

DETAILS OF FRAMING BETWEEN COLUMNS



CONNECTIONS FOR BEAMS AND GIRDERS

"Connection-angles shall in no case be less in thickness than the web of the b or girder to which they are fastened, nor shall the width be less than ⅓ the dept the beam, except that no angle-knee shall be less than 2½" wide nor required t more than 6" wide. Web-angles, the full depth of the web, must be used for all gi connections."

Fig. 12. Framing of Steel I Beams and Girders

Beam-Connections. Steel beams and channels are FRAMED together means of short pieces of angles, which are usually riveted to the floor-bea tail-beam and bolted to the girder. The angles are always used in pairs, on each side of the beam. If the floor-beam is framed flush, either with the to bottom of the girder, or if two beams of the same height are framed together, end of the beam supported should be COPED, or cut to fit the shape of the gi or supporting beam. The maximum clearance-space allowed between the

ab with that of the beam girder and coped to fit it, except where the girder is on a
ast 1¼ in below the beams so the latter may be ... Smaller beams
and coped. All openings in the floors, except ... the full width
all sides. Built-up girders are to be set with ... more than 5 in

CLAMPS or ANCHORS, and framed about 1 in above the upper flange of the bea to allow for settlement. If these joists are over 3 ft apart, short lengths of ang may be placed under each one.*

Standard Connection-Angles for I Beams and Channels. The size the angles and the number of rivets used for connecting steel beams, va somewhat with different shops and with different structural engineers, so th there cannot be said to be a universal standard. The variations in the diffe ent STANDARDS, however, are not very great, and as the connections adopt by the Carnegie Steel Company are perhaps the most used, the author has lected them for illustration in Table XVII. The CONNECTIONS have been p portioned with a view to covering most cases occurring in ordinary practi with the usual relations of depth of beam to length of span. In extreme stances, however, where beams of short relative span-lengths are loaded to th full capacity, or when beams frame opposite each other into another beam wi web-thickness less than $\frac{5}{16}$ in, it may be found necessary to make provision additional strength in the connections. The LIMITING SPAN-LENGTHS, al at and above which the standard connection-angles may be used with perfe safety, are also given in Table XVIII.

* For details of the framing of floor-beams and girders, see Chapters XXI and XX and also Professor Nolan's revised Chapters II and VII of Kidder's Building-Constructi and Superintendence, Part II, Carpenters' Work.

t = Web-thickness, in bearing, to develop maximum allowable reactions, wh beams frame opposite

Connections are figured for bearing and shear (no moment considered)

The above values agree with tests made on beams under ordinary conditions use

Where the web is enclosed between connection-angles (enclosed bearing), valu are greater because of the increased efficiency due to friction and grip

Special connections must be used when any of the limiting conditions giv above are exceeded, as when an end-reaction from a loaded beam is greater th the value of the connection of the shorter span with the beam fully loaded; or a l thickness of web when maximum allowable reactions are used

* From Pocket Companion, Carnegie Steel Company, Pittsburgh, Pa.

† For slight variations from these values, see Chapter XXVIII, Table I and Ch XXX, 4, Stresses.

CHAPTER XVI

STRENGTH OF CAST-IRON LINTELS AND WOODE BEAMS

By

F. H. KINDL

LATE CORRESPONDING MEMBER AMERICAN INSTITUTE OF ARCHITECTS

1. Cast-Iron Lintels

Form of Cross-Section. Owing to the fact that the resistance of cast i to tension is only about one-fifth of its resistance to compression, the shapes beams most economical for wrought iron or steel would be wasteful for c iron. The extreme brittleness of cast iron, and the danger of flaws in castin render it an undesirable material for resisting transverse stress. About t only form in which cast-iron beams are now used in building-construction this country is in the shape of LINTELS for supporting brick or stone walls, places where a flat soffit is desired, and the walls a not to be plastered. CAST-IRON LINTELS are a occasionally used over store-fronts, the face of t lintel being paneled and molded for architectu effect.

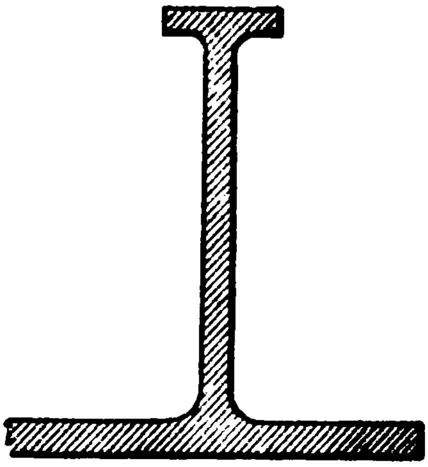

Fig. 1. Cross-section of Cast-iron Lintel of Ideal Form

Experiments on Cast-Iron Beams. Bef wrought-iron I beams were manufactured, CA IRON BEAMS were frequently used as the o available ones, other than those of wood or sto Early in the nineteenth century Eaton Hodgk son, an English engineer, made a series of exp ments with cast-iron beams, from which he fou that the form of cross-section of a beam of t material which will resist the greatest transve stress is that shown in Fig. 1, in which there is six times more metal in bottom than in the top flange. The relative thicknesses of the three parts, web, the top flange and the bottom flange, may be, with advantage, as 5, 6 a 8, respectively.

Strength of Cast-Iron Beams. If made with these proportions, the wi of the top flange will be equal to one-third that of the bottom flange. As result of his experiments, Hodgkinson gave the following rule for the breaki weight at the middle for a cast-iron beam of this form:

$$\text{Breaking-load in tons} = \frac{\left(\begin{array}{c}\text{area of bottom flange}\\ \text{in square inches}\end{array}\right) \times \left(\begin{array}{c}\text{depth}\\ \text{in inches}\end{array}\right) \times 2.426}{\text{clear span in feet}}$$

This rule, although largely empirical, agreed very well with the few exp ments that were made. Structural engineers, however, use the general form las for the strength of beams, as given in Chapter XV, except that the SECTI MODULUS is found by dividing the MOMENT OF INERTIA by the distance of neutral axis from the bottom of the beam, and the SAFE TENSILE STRENGT

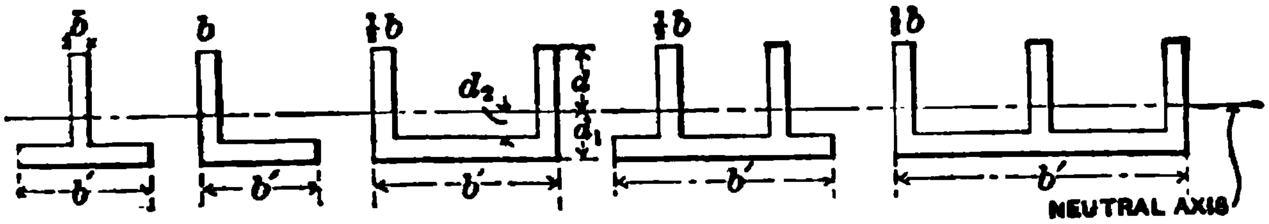
used in the FLEXURE-FORMULA. Thus the general formula for a beam supported at both ends and with the load uniformly distributed, as given in Chapter XV, page 560, is:

Safe load in pounds $= \frac{2}{3}\,\frac{I/c}{l} \times S_t$. As S_t, the safe tensile strength for cast iron should be taken at 3 000 lb, this formula becomes

$$\text{Safe load in pounds} = \frac{2\,000\,I/c}{l} \qquad (2)$$

and, for either section given below,

$$I/c = \frac{\text{Moment of inertia}}{d_1}$$



The MOMENT OF INERTIA is computed by the formula (see page 337)

$$I = \frac{bd^3 + b'd_1^3 - (b' - b)d_2^3}{3} \qquad (3)$$

in which b denotes the combined thickness of the webs, and the distances d, d_1 and d_2 are measured from the NEUTRAL AXIS, which must pass through the CENTER OF GRAVITY of the section. The center of gravity may be found by the method explained in Chapter VI. This formula may be used for any of the above sections when the depth does not exceed the width, and the thickness of each web is at least equal to the thickness of the flange. In lintels with a single web it is well to make the thickness of the web ¼ or ⅛ in greater than the thickness of the flange. For a beam with a cross-section like that shown in Fig. 1, Formula (2) agrees very closely with Formula (1), when a factor of safety of six is used.

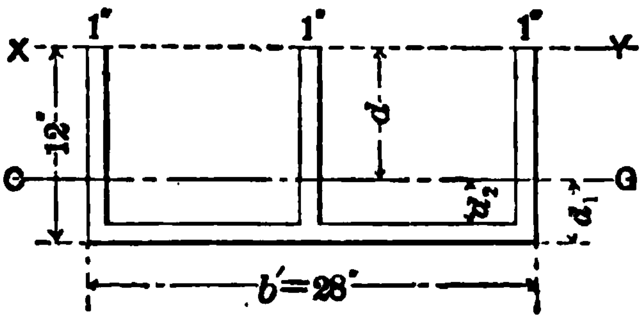


Fig. 2. Cross-section of Cast-iron Lintel with Three Webs

Example. The following example illustrates the application of Formula (3): It is required to compute the safe load for a cast-iron lintel having the section shown in Fig. 2 and a clear span of 10 ft. The load is uniformly distributed, and the thickness of the metal 1 in.

Solution. The first step is the finding of distance d, that the center of gravity, through which the neutral axis of the cross-section passes, is below the top surface of the beam. This is found by taking the moments of the areas of the cross-sections of webs and flange about the line XY, and dividing their sum by the area of the entire section. (See page 294.) Each web-section is 11 in long and 1 in thick; hence the area of each is 11 sq in. The MOMENTS OF THE THREE WEBS about XY will then be $3 \times 11 \times 5\frac{1}{2} = 181.5$

the MOMENT OF THE FLANGE about $XY = 28 \times 11\frac{1}{2} = 322$

$\quad 503.5$

The area of the entire cross-section = 61 sq in

$503.5 \div 61 = 8.25 = d$ in

Then	$d = 8.25$ in	$d^3 = 561.5$	$b = 3$ in
	$d_1 = 3.75$ in	$d_1^3 = 52.7$	$b' = 28$ in
	$d_2 = 2.75$ in	$d_2^3 = 20.8$	

The MOMENT OF INERTIA is next found by Formula (3):

$$I = \frac{3 \times 561.5 + 28 \times 52.7 - 25 \times 20.8}{3} = 880$$

$I/c = 880/3.75$. From Formula (2) the safe load = $(2\,000 \times 234.6)/10 = 46\,9$ lb, or 23.4 tons.

Ends and Brackets of Cast-Iron Lintels. When a lintel, the cross-tion of which has the shape of an inverted T (⊥), is used over a single opening,

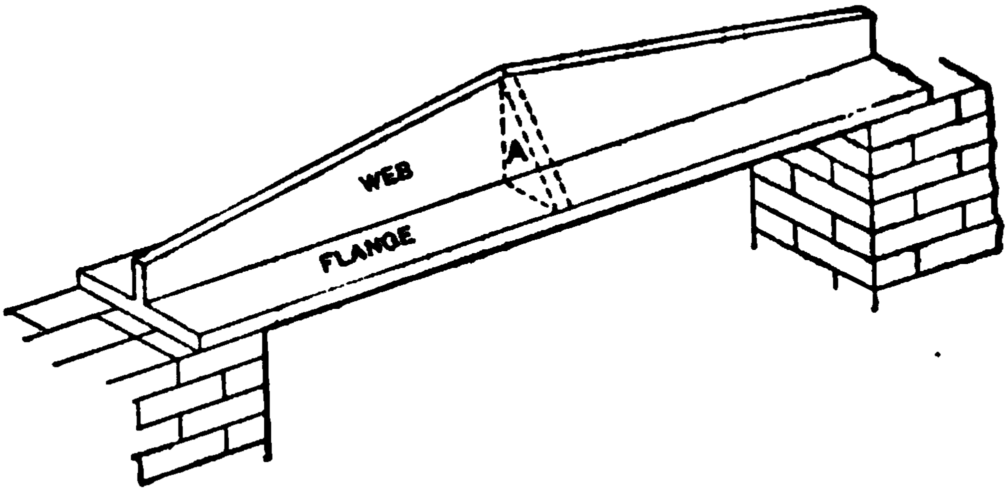

Fig. 3. Cast-iron Lintel with Tapering Web

web may be tapered towards the ends, as in Fig. 3, without affecting the streng If the flange is more than 8 in wide, brackets should be cast in the middle, a A, Fig. 3.

When CONTINUOUS LINTELS are used over store-fronts or similar pla ends should be cast on the lintels, as in Fig. 4, and the ends of abutting lin

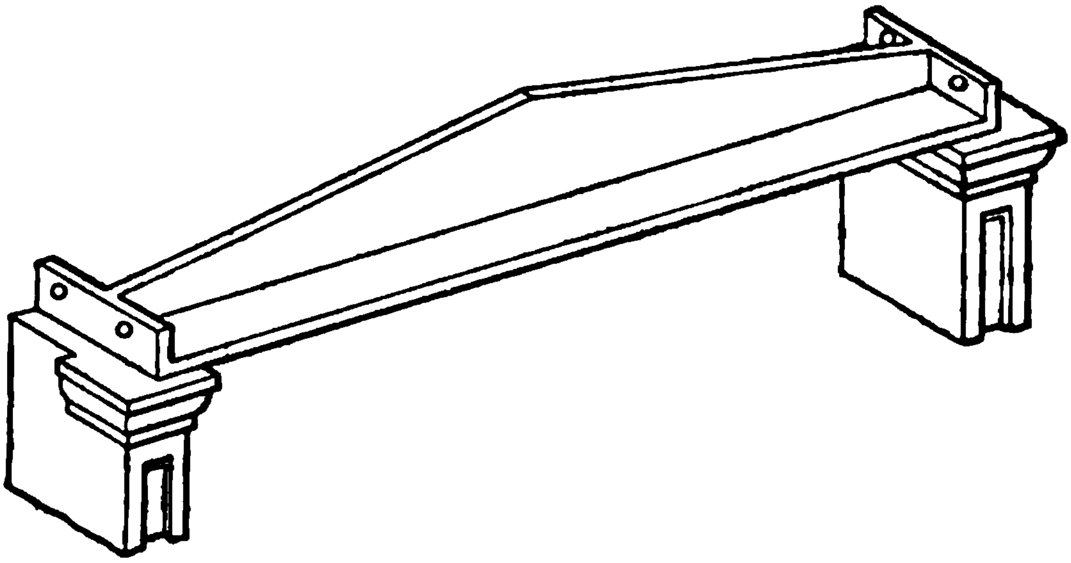

Fig. 4. Cast-iron Lintel with Ends for Bolting

bolted together. All lintels with two or three webs should have solid ends necting the webs.

Tables of Strength of Cast-Iron Lintels. The tables on the follo pages have been computed in accordance with Formula (2). The weight of

lintel itself should be deducted from the safe load. In using these tables it should be remembered that the values are for loads UNIFORMLY DISTRIBUTED. If the load is CONCENTRATED AT THE MIDDLE, it should be multiplied by 2. If at some other point than the middle, the load should be multiplied by the value given on pages 566 and 632, which most nearly corresponds with the position of the load. For other spans than those given, the distributed load should be multiplied by the span, and the lintel used which has a COEFFICIENT OF STRENGTH C (Table I) just above the product thus obtained. (For explanation of coefficient of strength, see Chapter XV, page 556.)

Example. It is required to support a 12-in brick wall, 10 ft high, over an opening 5 ft 6 in wide, with a cast-iron lintel. At a distance of 22 in from one support, a girder, which may bring a load of 9 600 lb on the lintel, enters the wall. What should be the dimensions of the lintel?

Solution. At 110 lb per cu ft, the wall above the lintel weighs $10 \times 5\frac{1}{2} \times 110 = 6\,050$ lb. As 22 in is one-third of the span, the concentrated load is multiplied by 1.78 (page 632), making the load 17 088 lb. The total equivalent distributed load is then 23 138 lb. Multiplying this by the span there results 127 259 lb, or 63.6 tons, as the least value for the coefficient of strength *C*. From the table, it is found that a 12 by 10-in lintel, 1 in thick, with one web, has a coefficient of strength of 72.2; and that a 12 by 8 by $1\frac{1}{4}$-in lintel with two webs, has a coefficient of strength of 69.9. A lintel with two webs is best for a 12-in wall, and interpolating between the values of *C* for the 1-in and 2-in thicknesses of the 12 by 8-in lintel, 65.4 is found to be the value of *C* for a thickness of $1\frac{1}{8}$ in. This exceeds the required value by enough to more than compensate for the weight of the lintel itself; hence a 12 by 8 by $1\frac{1}{8}$-in lintel with two webs is used.

Flaws in Castings. Owing to the liability of flaws in the castings, cast-iron lintels should always be carefully inspected before being accepted.

Table I. Safe Distributed Loads in Tons for Cast-Iron Lintels

LINTELS OF  SHAPES

Loads include weights of lintels. Maximum tensile stress 3 000 lb per sq in. remarks, pages 622 and 623.

3. Sections, Stresses, Buckling and Deflection of Wooden Beams and Girders

Sections and Fiber-Stresses. The cross-sections of wooden beams are almost invariably SQUARE OR RECTANGULAR, and those shapes only are considered in the following rules and formulas. Beams should have such a cross-section, that the maximum fiber-stress due to transverse bending, the maximum horizontal shear and the compression across the grain at the end-bearings do not exceed the AVERAGE ALLOWABLE UNIT STRESSES as set forth in Table XVI.

Buckling. Wooden girders should be braced laterally to prevent BUCKLING when the ratio of length to breadth exceeds twenty, or designed with a reduced fiber-stress from that allowable, where this ratio is exceeded. Tables VII to XV assume such bracing. Joists should have bridging not over 8 ft on centers. The PERCENTAGE OF REDUCTION of fiber-stress for girders should be as follows:

Ratio of length to width.....	20 to 30	30 to 40	40 to 50	50 to
Percentage of reduction......	25	34	42	50

Deflection. It is also important that beams carry the loads without DEFLECING beyond a limit fixed by the use to which the structure is applied; this lir is generally taken at 1/30 of an inch per foot of span for plastered ceilings.

3. Constants and Coefficients for Beams

Value of the Constant, A. The letter *A* in the following formulas (4) (16), denotes the SAFE LOAD for a UNIT BEAM, 1 in square in section and 1 ft span, loaded at the middle of the span. This is also one-eighteenth of t ALLOWABLE FIBER-STRESS in pounds per square inch. (See Table I, on pa 557.) The following are the values of *A*, obtained by dividing by eighteen t RECOMMENDED UNIT STRESSES for TRANSVERSE BENDING, and those given in t building laws of New York, Chicago, Baltimore and Boston.

Table II.* Coefficients for Iron, Steel and Wooden Beams. Values for A Formulas

Materials	New York	Chicago	Baltimore	Boston	Recommended
Cast iron	167	167	167	167	167
Wrought iron	667	667	667	667	667
Steel	889	889	889	889	889
Yellow pine	90	72	100	83	67
White pine	67	44	56	56	39
Spruce	67	44	75	56	39
Hemlock	44	33	....	....	33
Chestnut	....	....	....	....	44
Oak	67	67	83	56	67
Douglas fir	67	72	....	....	56

* For safe allowable working unit stresses for other woods, see Table XVI, page (From these values, *A* may be determined by dividing them by eighteen. See Ta XVII, page 648, for other stresses for woods, taken from various building laws. Tables XVIII and XIX, pages 650 and 651, for the ultimate strength of woods.

† The values of *A* for wooden beams may be increased from 30 to 40% for tempor structures, and for commercially dry and protected timber, not subject to impact, or ideal conditions.

Table III. Coefficients Recommended for Stone ‡ and Concrete Beams. Values of A

Materials	Values of *A*	Materials	Values of *A*
Granite	10	Bluestone	17
Limestone	8	Slate	22
Marble	7	Concrete 1 : 2 : 4	1.
Sandstone	6	Concrete 1 : 2 : 5	1.

‡ Values of *A* for STONE BEAMS were taken from former Building Laws of New Y and from the requirements of the Board of Fire Underwriters.

4. Flexural Strength of Wooden Beams

Section-Modulus. For beams with a rectangular cross-section, the formulas for strength can be simplified by substituting for the SECTION-MODULUS its value $\frac{1}{6} bd^2$, where b is the breadth and d the depth of the section.

Substituting this value in the general formulas for beams with rectangular cross-sections and of any material, the following formulas result:

Beams Fixed at One End and Loaded at the Other (Fig. 5).

$$\text{Safe load, in pounds} = \frac{\text{breadth} \times \text{square of depth} \times A^*}{4 \times \text{length in feet}} \tag{4}$$

$$\text{Breadth, in inches} = \frac{4 \times \text{load} \times \text{length in feet}}{\text{square of depth} \times A^*} \tag{5}$$

Fig. 5. Cantilever Beam. Load near Free End

Fig. 6. Cantilever Beam. Distributed Load over Entire Span

Beams Fixed at One End and Loaded with a Uniformly Distributed Load (Fig. 6).

$$\text{Safe load, in pounds} = \frac{\text{breadth} \times \text{square of depth} \times A^*}{2 \times \text{length in feet}} \tag{6}$$

$$\text{Breadth, in inches} = \frac{2 \times \text{load} \times \text{length in feet}}{\text{square of depth} \times A^*} \tag{7}$$

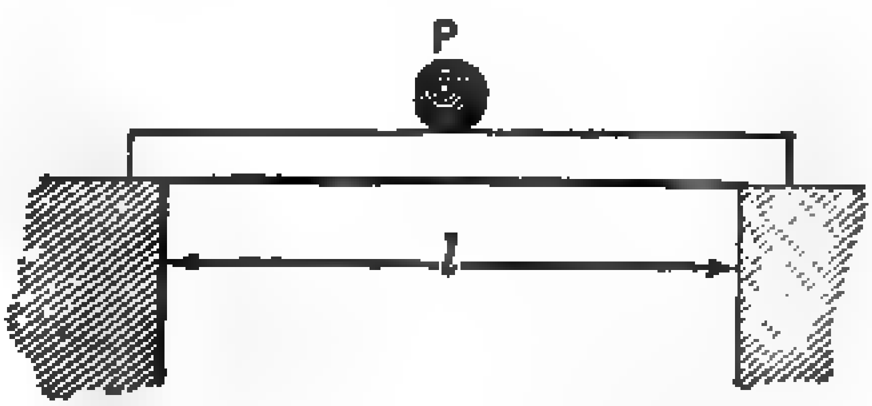

Fig. 7. Simple Beam. Load at Middle of Span

Beams Supported at Both Ends and Loaded at the Middle (Fig. 7).

$$\text{Safe load, in pounds} = \frac{\text{breadth} \times \text{square of depth} \times A^*}{\text{span in feet}} \tag{8}$$

$$\text{Breadth, in inches} = \frac{\text{span in feet} \times \text{load}}{\text{square of depth} \times A^*} \tag{9}$$

* For values of A, see Tables II and III.

Beams Supported at Both Ends and Loaded with a Uniformly Distribu Load Over Entire Span (Fig. 8).

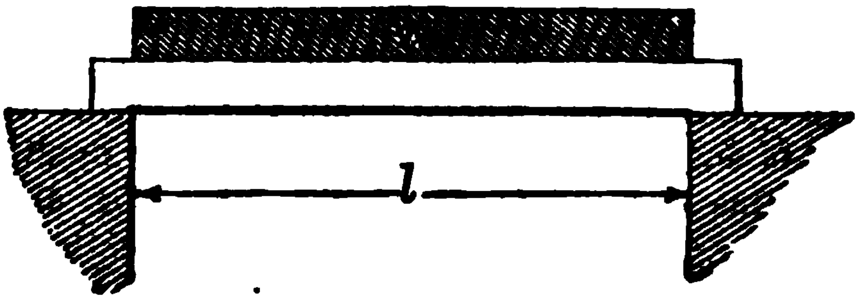

Fig. 8. Simple Beam. Distributed over Entire Span

$$\text{Safe load, in pounds} = \frac{2 \times \text{breadth} \times \text{square of depth} \times A^*}{\text{span in feet}}$$

or

$$\text{Breadth, in inches} = \frac{\text{span in feet} \times \text{load}}{2 \times \text{square of depth} \times A^*}$$

Beams Supported at Both Ends and Loaded with a Uniformly Distrib Load Over Only a Portion of the Span (Fig. 9).

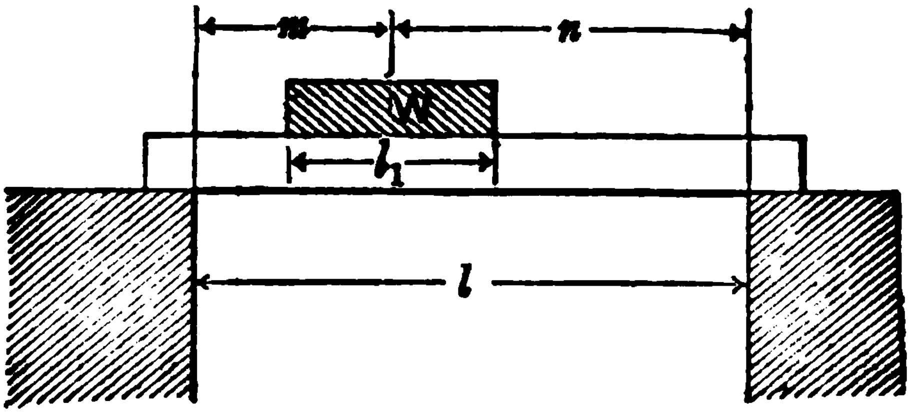

Fig. 9. Simple Beam. Distributed Load over Part of Span

In this case the dimensions of the beam required to carry the load ca accurately determined only by computing the MAXIMUM BENDING MOMEN explained in Chapter IX, and substituting the value thus found in Formula following. If, however, the length l_1 is very short in comparison with l, near the middle, then the load may be considered as CONCENTRATED at the mi of the span and the breadth of the beam may be found by Formula (9). mula (13) is used if the load is at one side of the middle. The error will b the safe side.

Beams Supported at Both Ends and Loaded with Concentrated Load, at the Middle of the Span (Fig. 10).

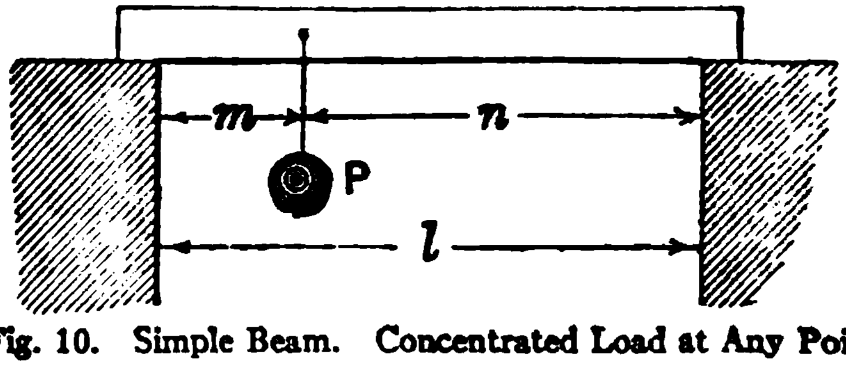

Fig. 10. Simple Beam. Concentrated Load at Any Point

$$\text{Safe load, in pounds} = \frac{\text{breadth} \times \text{square of depth} \times \text{span} \times A^*}{4 \times m \times n}$$

or

$$\text{Breadth, in inches} = \frac{4 \times \text{load} \times m \times n}{\text{square of depth} \times \text{span} \times A^*}$$

* For values of A, see Tables II and III.

Beams Supported at Both Ends and Loaded with P Pounds at a Distance m from each End (Fig. 11).

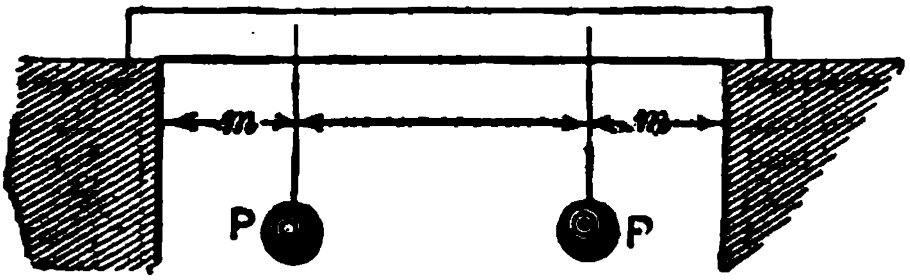

Fig. 11. Simple Beam. Two Equal Concentrated Loads Symmetrically Placed

$$\left.\begin{matrix}\text{Safe load, } P\text{, in pounds}\\ \text{at each point}\end{matrix}\right\} = \frac{\text{breadth} \times \text{square of depth} \times A^*}{4 \times m} \qquad (14)$$

$$\text{Breadth, in inches} = \frac{4 \times \text{load at one point} \times m}{\text{square of depth} \times A^*} \qquad (15)$$

Note. In the last two cases the lengths denoted by *m* and *n* should be in feet, as the spans are in feet.

8. Application of Formulas for Flexural Strength of Wooden Beams

Example 1. What load, 6 ft out from the wall, will an 8 by 14-in long-leaf yellow pine beam, securely fastened at one end into a brick wall, sustain with safety?

Solution. The safe load in pounds (Formula 4) $= \dfrac{8 \times 196 \times 67}{4 \times 6} = 4\,377$ lb

Example 2. It is desired to suspend two loads of 10 000 lb each, 4 ft from each end of an oak beam, 20 ft long. What should be the size of the beam?

Solution. Let the depth of the beam be assumed to be 16 in. Then (Formula 15)

$$\text{The breadth} = \frac{4 \times 10\,000 \times 4}{256 \times 67} = 9.3 \text{ in, nearly}$$

The beam, therefore, should be 10 by 16 in in cross-section.

Beam with Several Loads. It is required, next, to determine the size of a beam which is supported at both ends, and which will safely support several concentrated loads, or a distributed load and one or more concentrated loads. The correct method of finding the least size of a beam that will safely support a combination of loads, is to first find the MAXIMUM BENDING MOMENT, as explained in Chapter IX, page 329, and then substitute the value thus found for this BENDING MOMENT in the following formula:

$$\text{Breadth, in inches} = \frac{4 \times \text{maximum bending moment in ft-lb}}{\text{square of depth} \times A} \qquad (16)$$

A shorter and easier method is to find the EQUIVALENT DISTRIBUTED LOAD for each concentrated load, and then find the size of a beam required to support the total equivalent distributed load thus found. The equivalent distributed loads for concentrated loads applied at different proportions of the span from either end, may be obtained by multiplying the concentrated loads by the following FACTORS:

* For values of *A*, see Tables II and III.

Table IV. Factors for Equivalent Distributed Loads

	Position of load	Factor
For a concentrated load	Applied at middle of span	Multiply by 2.
For a concentrated load	Applied at one-third the span	Multiply by 1.
For a concentrated load	Applied at one-fourth the span	Multiply by 1.
For a concentrated load	Applied at one-fifth the span	Multiply by 1.
For a concentrated load	Applied at one-sixth the span	Multiply by 1
For a concentrated load	Applied at one-seventh the span	Multiply by 0
For a concentrated load	Applied at one-eighth the span	Multiply by
For a concentrated load	Applied at one-ninth the span	Multiply by 0.
For a concentrated load	Applied at one-tenth the span	Multiply by 0.

(See, also, Chapter XV, Safe Loads for Steel Beams, page 566.)

Thus, a concentrated load of 900 lb, applied at one-sixth the span from support, will result in the same maximum bending moment as a distrib load of 900 × 1⅑, or 1 000 lb.

The above method for finding the size of a beam for a combination of sev loads gives a larger beam than the correct method, by Formula (16), for reason that the maximum bending mom will not be equal to the sum of the dividual bending moments. Hence, w there are several heavy loads to be s ported, it is economical to compute maximum bending moment by the GRAI METHOD explained in Chapter IX, p 329.

Fig. 12. Girder with Three Concentrated Loads

Example 3. The girder *G*, Fig. 12, s ports the rafters of a flat roof, and three heavy beams, *A*, *B* and *C*, blocked above the roof and supporting a large t filled with water. The timber is to long-leaf yellow pine. The weight of the roof and allowance for snow is 7 lb. Each of the beams *A*, *B* and *C*, impose a load on the girder, due to weight of the tank and its contents, of 3 000 lb. What should be the size o girder?

Solution. The roof-load may be considered to be uniformly distribu The load from beam, *A*, is applied at one-third the span from one end; the from *B*, five-twelfths the span from the other end; and the load from *C*, sixth the span. The fraction five-twelfths is the mean of one-half and one-t hence the load from *B* should be multiplied by 1.89. Multiplying the centrated loads by their proper factors, the equivalent distributed load is f to be as follows:

Roof-load, distributed,	=	7 500
Load from *A*, 3 000 × 1.78	=	5 340
Load from *B*, 3 000 × 1.89	=	5 670
Load from *C*, 3 000 × 1⅑	=	3 333
Equivalent distributed load	=	21 843 lb

Assuming 16 in as the depth of the beam, and using Formula (11),

$$\text{The breadth} = \frac{12 \times 21\,843}{2 \times 256 \times 67} = 7.6 \text{ in}$$

Assuming 14 in for the depth, 10 in is obtained for the breadth; hence, the girder must be 10 by 14 in, or 8 by 16 in in cross-section.

Strut-Beams and Tie-Beams. A STRUT-BEAM is a beam that is subject to both a transverse and a compressive stress. A TIE-BEAM is one that is subject to direct tension in addition to the transverse stress. To find the strength of either, first find the size of a beam required to resist the transverse stress, and then the size of a timber, of the same depth as the beam, to resist the direct tension or compression, and add the two breadths together.

Example 4. A spruce tie-beam, 10 ft long between joints, sustains a ceiling-load of 2 000 lb and a direct tensile stress of 40 000 lb. What should be the dimensions of the beam?

Solution. As a ceiling-load is uniformly distributed, the size of the beam is determined by Formula (11), page 630. Assuming the depth to be 10 in

$$\text{The breadth} = \frac{10 \times 2\,000}{2 \times 100 \times 39}, \quad \text{or} \quad 2\tfrac{1}{2} \text{ in, nearly}$$

The resistance of spruce to tension (see Table XVI, page 647) is 800 lb per sq in. 40 000/800 = 50 sq in, which is equivalent to a 5 by 10-in section. It will require, therefore, a beam 7½ by 10 in in cross-section to resist both the transverse stress and the direct tension. If the tie-beam is cut in any way so as to reduce the section, except over a support, the dimensions must be increased accordingly.

Example 5. A strut-beam of white pine, 10 ft long, supports a distributed roof-load of 6 000 lb, and is also subject to a direct compression of 64 000 lb. What should be the size of the beam?

Solution. Assuming 14 in for the depth, the breadth for the transverse load is found by Formula (11), page 630

$$\text{The breadth} = \frac{10 \times 6\,000}{2 \times 196 \times 39} = 3.9 \text{ in, nearly}$$

Using Formula (4), page 450, from which is computed Table IV, page 452, giving the safe loads for white-pine posts, it is found that a 7½ by 14-in post, 10 ft long will safely carry the compressive stress, 64 000 lb. Hence it will require a 7½ by 14-in beam to resist the compressive stress, and a 4 by 14-in beam to resist the transverse load. The beam, therefore, should be 12 by 14 in in cross-section to resist them both.

6. Relative Strengths of Beams

Relative Strengths of Rectangular Beams. From an inspection of the foregoing formulas it is found that the RELATIVE STRENGTHS of beams of rectangular cross-sections, for the different cases is as shown in Table V.

Strengths of Beams of Any Constant Cross-Section. The STRENGTH-RATIOS given in Table V are true for beams of any constant cross-section of whatever form.

Beam on Edge. When a beam of square cross-section is supported on its edge, that is, when one of its diagonals is vertical, it will bear about seven-tenths as great a breaking-load as it will when it is supported on one side.

Table V. Relative Strengths of Rectangular Beams

Kind of load	Position of load	Strength ratios
Beam supported at both ends		
Uniformly distributed	Over entire span	1
Concentrated	At middle of span	1/2
Concentrated	At one-third the span	9/16
Concentrated	At one-fourth the span	2/3
Concentrated	At one-fifth the span	25/32
Concentrated	At one-sixth the span	9/10
Concentrated	At one-seventh the span	49/48
Concentrated	At one-eighth the span	8/7

The Strongest Beam Cut From a Cylindrical Log is one in which breadth is to the depth as 5 is to 7, very nearly, and the dimensions of such a b can be found graphically, as shown in Fig. 13. Any diagonal, as *ab*, is di and divided into three equal parts by the points *c* *d*; from these points lines perpendicular to *ab* are dr and the points *e* and *f* connected with *a* and *l* shown.

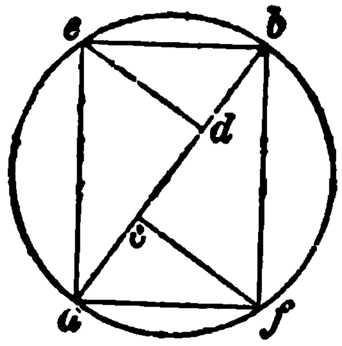

Fig. 13. Strongest Beam of Rectangular Section Cut from Log

Cylindrical Beams. A CYLINDRICAL BEAM is ten-seventeenths as strong as a beam with a sq cross-section, the side of the square being equal to diameter of the circular section of the cylindrical b Hence, to find the safe load for a cylindrical beam, find the proper load for the corresponding sq section beam, and divide this load by 1.7.

The Bearing of the Ends of a Beam on a beyond a certain distance does not strengthen the beam. In general, a l should have a bearing of 4 in, or if it is very long, 6 in.

The Weight of the Beam Itself. The formulas given for the strengt beams do not take into account the WEIGHT OF THE BEAMS THEMSELVES, hence the safe loads of the formulas include both the external loads and weights of the material in the beams. In small wooden beams, the weig

each beam is generally so small, compared with the external load, that it need not be taken into account. But for larger wooden beams, and for metal and stone beams, the weight of the beam should be subtracted from the safe load if the load is distributed; and if the load is applied at the middle, one-half the weight of the beam should be subtracted.

The Weight of Timber. The weight per cubic foot for different kinds of timber may be found in the table in Part III, pages 1501 to 1508, giving the Weights of Various Substances.

7. Tables for Strength and Stiffness of Wooden Beams

Tables VII to XV for the Strength and Stiffness of Wooden Beams are given on pages 638 to 646, for BEAMS ONE INCH IN BREADTH. To find the length for any other breadth, multiply the proper tabular value by the breadth of the beam in inches. To obtain the required breadth for any load, divide the given load in pounds by the proper tabular value. In heading the tables, prominence has been given to the values used for S, and the corresponding values of A, so that those who prefer to use for any wood a value different from that recommended, need only to look up the table based on the value they desire to employ. For certain cases and in some cities, the building laws specify 1 300, 1 500 and 1 800 pounds as values of S to be used for long-leaf yellow pine; hence Tables XIII, XIV and XV, based on these values, are added.

Since timber is weak in HORIZONTAL SHEAR compared with its strength in TENSION and COMPRESSION, the safe load a beam of short span can carry is governed, not by its resistance to CROSS-BREAKING, but by its RESISTANCE to SHEARING along the NEUTRAL SURFACE. Wooden beams and joists, therefore, should be dimensioned to safely withstand this SHEARING ACTION. The ratio of the SHEARING to the FLEXURAL STRENGTH is not exactly the same for different kinds of wood, but for practical use and in the tables it has been assumed to be one-twelfth of the WORKING UNIT FIBER-STRESS. As it can be shown * that the ratio of the span to the depth of a rectangular beam, uniformly loaded, is directly proportional to its CROSS-BREAKING STRESS and SHEARING WORKING STRESS, the tabular loads are figured for the PERMISSIBLE UNIT FIBER-STRESS, where the length of the span is twelve or more times the depth of the beam; while for shorter lengths, the tabular loads are governed by the SHEAR. To determine the safe load on beams for a deflection not exceeding 1/360 of the span, tabular values have been placed directly underneath the safe loads for strength. These values are based on the MODULUS OF ELASTICITY, E, given in the tables.

The FORMULA FOR FLEXURE used in determining the safe uniformly distributed loads in the tables is (see Formulas (1), page 333 and (2)′, page 557)

$$M = \frac{SI}{c} = \frac{Sbd^2}{6} = \frac{Wl}{8}$$

hence

$$W = \frac{4}{3}\frac{bd^2S}{l}, \text{ in which } l \text{ is the span in inches}$$

The FORMULA FOR SHEAR is

$$W = \frac{4\,bdS_s}{3}$$

* Materials of Construction, J. B. Johnson, page 55.

The FORMULA FOR DEFLECTION is (see, also, Formulas (1) to (17) and Tal
Chapter XVIII)

$W = \dfrac{Ed^3}{8\,100\,l^2}$ in which l is the span in feet;
M = maximum bending moment in inch-pounds;
I = moment of inertia of the cross-section of the beam in biquadr
inches;
$c = d/2$ = one-half the depth of the beam in inches;
SI/c = resisting moment of the cross-section in inch-pounds;
W = total safe load in pounds, uniformly distributed;
b = breadth of the beam in inches;
d = depth of the beam in inches;
l = span, in feet or inches, as noted for the different formulas;
S = unit flexural fiber-stress in pounds per square inch;
$S_s = S/12$ = horizontal unit shearing-stress, in pounds per square inch, along
neutral surface;
E = modulus of elasticity in pounds per square inch.

Example 6. What is the safe, uniformly distributed load, correspondin
a fiber-stress of 1 500 lb per sq in, for an 8 by 14-in long-leaf yellow-pine b
supported at both ends, and having a 24-ft clear span?

Solution. From Table XIV, the load for a 1-in thickness is 1362 lb. He
1 362 × 8 = 10 896 lb, the total load for the beam. If the deflection of
beam should not be more than 1/360 of the span, the safe load for 1-in thick
should not exceed 882 lb. Hence, 882 × 8 = 7 056 lb, is the maximum loa
be used in this case. It is assumed that 1 500 lb per sq in is allowed for

Example 7. What should be the size of a Norway-pine beam required to c
a distributed load of 6 400 lb over a clear span of 18 ft?

Solution. From Table X, it is found that a beam 12 in deep and 1 in
and with an 18-ft span, will support 711 lb. Dividing the load, 6 400 lb
711, the result is 9 for the breadth of the beam in inches. Hence the b
should be 9 by 12 in, to carry a distributed load of 6 400 lb over a span of
As the deflection-load of 593 lb can be increased 20% for Norway pine, the b
is safe for deflection; if, however, cypress is used, 593 must be taken in pla
711, to determine the breadth of the beam. This would result in a bea
by 12 in.

Different Positions of Loads. To find the safe load, concentrated a
middle of the span of a given beam, find the safe distributed load, as in Exa
6, and divide this load by 2. To find the safe load concentrated at
point other than the middle of the span, find the safe distributed load fo
given span, and divide this load by the proper factor taken from Tabl
page 632. To find the size of a beam to support a given concentrated
multiply the given load by the factor corresponding to the position of the
as given in Table IV, and then proceed as in Example 7.

Use of Formulas. If in doubt as to the application of the tables, in s
cases, use one of the formulas, from (4) to (16), applying to the case.
formulas and tables should always give the same result.

Nominal and Actual Sizes of Beams. The tables may be used for
the dimensions of which are less than the NOMINAL DIMENSIONS. D
beams, and, in many localities, floor-joists carried in stock, are more
scant of the nominal dimensions, and for such beams and joists a reduct
the safe load must be made to correspond with the reduction in size.

...SED SIZES are generally 1/4 in scant, up to 4 in in breadth, above which they ...e 1/2 in scant; while in depth they are all generally 1/2 in less than the nominal ...e. The safe loads may be obtained by multiplying the safe loads for the ...responding nominal sizes, as given in Tables VII to XV, by the factors given ...the following table.

Table VI. Conversion Factors for Actual Sizes of Wooden Beams

Cross-sections of beams in inches	Factors	Cross-sections of beams in inches	Factors
1¾×5½	1.47	1¾×11½	1.61
2¾×5½	2.31	2¾×11½	2.53
1¾×6½	1.51	1¾×13½	1.63
2¾×6½	2.51	2¾×13½	2.56
1¾×7½	1.54	1¾×15½	1.65
2¾×7½	2.42	2¾×15½	2.58
1¾×9½	1.53	1¾×17½	1.65
2¾×9½	2.48	2¾×17½	2.60

...ample 8. What is the safe load for a 2¾ by 13½-in spruce beam, with ...18-ft span?

...lution. From Table VIII, the safe load for a 1 by 14-in beam is 847 lb. ...ltiplying this by 2.56, we have 2 178 lb as the safe distributed load for a ...m 2¾ by 13½ in in cross-section. For a full 3 by 14-in cross-section, the ...e load would be 2 541 lb.

Stone Beams. The above formulas may be used for rectangular stone ...ms when the proper coefficients, recommended in Table III, page 628, are ...ted. Sandstone beams should never be subjected to any heavy loads and ...dstone lintels should be relieved by steel beams or by brick arches over them ...back of them.

Concrete Beams are generally reinforced with steel rods, but when used ...out reinforcement, the coefficient, A, given in Table III, is recommended.

...e of Tables VII to XV. The safe loads given in Tables VII to XV ...correct for the fiber-stresses indicated; but for greater convenience in using ...tables, each figure in the units-place of each value may be made a cipher, ...each figure in the tens-place may be increased by one when the unit-figure ...5 or greater. Thus, 505 would be 500, 506 would be 510, etc.

...portant Notes on Stresses and Loads for Wooden Beams. In compiling and ...the tables of safe loads for wooden beams, the following important considerations ...be kept in mind:

...) Unseasoned timber is very much weaker than commercially dry timber, that is, ...er containing from 10 to 15% of moisture.
...) Timber containing large or loose knots is much weakened.
...) When impact has to be considered, the stresses should be reduced.
...) For continuous, heavy loading, relatively low stresses should be used.
...) Commercial dimensions are smaller than nominal dimensions.
...) Timbers deteriorate and the factors of safety for strength grow smaller with time.
...) The modulus of elasticity, E, for unseasoned timber, should be reduced 50% from ...lue given for thoroughly seasoned timber.
...) It is better engineering practice to compute tables of safe loads based on conserva-...stresses for average or poor conditions, increasing the values given when conditions ...ideal, than to recommend values for ideal conditions which usually do not exist. ...notes, pages 628 and 647, regarding increase in the table-values.) Editor-in-Chief.

29	....	....	....	....	1 352	1 766	2 235
30	....	....	....	....	1 307	1 707	2 160

Loads above the heavy, black zigzag lines are calculated for resistance to shear.

For safe deflection-loads, see values in Tables VII to XII, according to the value of used, and determined by the deflection-formula, page 636.

8. Working Unit Stresses for Average, Unseasoned Woods

Safe Working Unit Stresses for unseasoned woods (except for E) are given in Table XVI. They are compiled and adapted largely from recommended UNIT STRESSES adopted by the Association of Railway Superintendents of Bridges and Buildings and by the American Railway Engineering Association. (See, also, page 449.)

Table XVI. Safe Working * Unit Stresses for Unseasoned Woods, in Pounds per Square Inch

Kind of wood	Tension		Compression			Bending †		Shearing

* The stresses given, except for E, may be increased 30% for protected, commercially dry timber, not subject to impact, as in most buildings.

† See also, Table I, page 557, Table XVII, page 648, and Table I, page 1138.

‡ The larger end-bearing stresses are frequently used for short columns and for column-formulas. (See tables, pages 449, 1138.) Lower factors of safety give higher stresses.

§ Some of these values are considered too low, relatively, by some building codes.

‖ These values of E are for seasoned timber. For unseasoned timber, reduce E [illegible]%.

¶ The New York Building Code (1917) stresses for these are 1 200 lb per sq in.

9. Working Unit Stresses for Woods. Taking from Building Laws.

The Allowable Working Unit Stresses for different woods, taken from the building laws of four cities, are given in Table XVII. The UNIT STRESSES are for TENSION, COMPRESSION, BENDING and SHEAR.

10. Ultimate Unit Stresses for Woods

The Average Ultimate Unit Stresses for the CONIFEROUS or SOFTWOODS and for the BROAD-LEAVED or HARDWOODS, together with the AVERAGE WEIGHTS of the woods per cubic foot are given in Tables XVIII and XIX. The values given are compiled from many tests on numerous species of timber. In regard to the range of values for the same kind of wood, it may be stated that the higher values are for specimens which contained a percentage of water varying from 15 to 20%; and that tests on laboratory specimens showed greater strength than the actual pieces used in construction. The WEIGHTS PER CUBIC FOOT are averages of the weights of many specimens tested and agree generally with average values given in other tables of weights of materials.

Table XVIII.* Average Ultimate Unit Stresses for the Coniferous or Softwoods, in Pounds per Square Inch

Kind of wood	Weight in lb per cu ft, dry	Tension	Compression		Bending (modulus of rupture)	Shear	
			With the grain	Across the grain		With the grain	Acros[illegible] the grain
Cedar (white).......	19.72 to 20.70	8 000 to 11 400	4 000 to 6 000	700	5 000	400	1 30[illegible] to 1 51[illegible]
Cedar (red).........	23.66	8 000	4 000 to 7 000	700	5 000	......	1 50[illegible]
Cypress............	29.80	4 000 to 6 000	4 000 to 8 000	700 to 800	5 000 to 11 700	500	.....
Hemlock...........	26.42 to 32.29	6 000 to 8 700	4 000 to 7 420	600 to 700	3 500	350	2 50[illegible] to 2 75[illegible]
Pine (white)........	25.55	3 000 to 12 000	3 000 to 6 650	700 to 1 000	4 000 to 10 000	225 to 423	2 48[illegible]
Pine (red), (Norway pine)............	30.25	5 000 to 13 000	6 000 to 8 000	800 to 1 000	5 000 to 12 300	500	.....
Pine (yellow), (long-leaf)............	43.62	6 000 to 13 000	5 000 to 9 500	1 000 to 1 400	7 000 to 14 200	300 to 700	4 34[illegible] to 5 00[illegible]
Pine (yellow), (short-leaf)............	38.40	5 000 to 10 000	4 000 to 9 000	900 to 1 000	6 000 to 12 400	400 to 700	4 00[illegible] to 5 00[illegible]
Douglas fir (Oregon pine)............	32.14	9 000 to 14 000	4 880 to 9 800	800 to 1 200	6 500 to 12 100	500 to 600	.....
Redwood (California)	26.23	7 000 to 10 853	3 000 to 4 000	800	4 500	400	......
Spruce (black)......	28.57	5 000 to 19 500	4 000 to 7 850	700	4 000 to 12 000	250 to 400	3 25[illegible]
Spruce (white)......	25.25	5 000 to 19 500	4 000 to 7 850	700	4 000 to 12 000	250 to 400	3 25[illegible]

* The higher values of tensile and compressive strengths are for " dry " or " se[illegible]oned " timber containing from 10 to 15% of water. For safe fiber-stresses f[illegible] lexure, see Table I, page 557.

Table XIX.* Average Ultimate Unit Stresses for the Broad-Leaved or Hardwoods, in Pounds per Square Inch

Kinds of wood	Weight in lb per cu ft, dry	Tension	Compression		Bending (modulus of rupture)	Shear

* The higher values of the tensile and compressive strengths are for "dry" or "seasoned" timber containing from 10 to 15% of water. For safe fiber-stresses for use, see Table I, page 557.

CHAPTER XVII

STRENGTH OF BUILT-UP, FLITCHED AND TRUSS[E]D WOODEN GIRDERS

By
F. H. KINDL
LATE CORRESPONDING MEMBER AMERICAN INSTITUTE OF ARCHITECTS

1. Built-Up Wooden Girders

Built-Up Wooden Beams. Wooden beams or girders built up of pla[nks] spiked or bolted together side by side, will generally be somewhat stron[ger] than solid girders of the same dimensions, because the planks will be be[tter] seasoned and freer from check-cracks and other defects. For beams or gir[ders] 10 in or less in depth, spikes will usually be sufficient to bind the planks toget[her] but for deeper beams, bolts should be used in addition to the spikes, to prev[ent] the planks from separating and the outer planks from warping or curling a[way] from the others.

Bolts. Two bolts should be placed at each end of the beam and every [...] feet of its length.

Lengths of Planks. When a beam is built up in this way each pl[ank] should extend the full length of the beam. In a CONTINUOUS BEAM, the pla[nks] should break joints over the supports. The planks of BUILT-UP BEAMS sh[ould] always be set on edge, never flatwise.

Compound Wooden Beams. It is sometimes necessary to use a woo[den] beam for a longer span or greater load than is safe for the deepest SINGLE B[EAM] that can be obtained, or for a beam built up of planks. In such cases COMPO[UND] WOODEN BEAMS may be used.

Definition. By a COMPOUND WOODEN BEAM or GIRDER is meant a b[eam] built up by placing two or more single beams over another one, with the [...] of having them act [...] SINGLE BEAM having [...] depth of the comb[ined] beams.

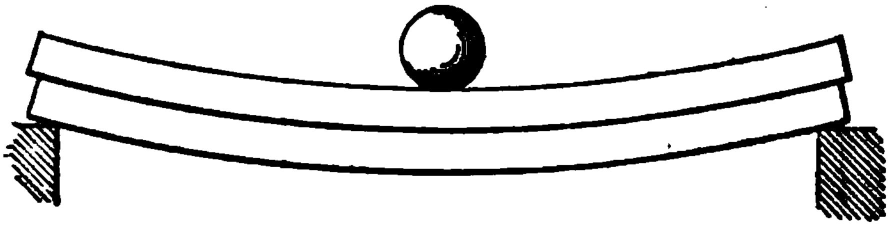

Fig. 1. Two Simple Wooden Beams, One Over the Other, Loaded in Middle

Strength of Co[m]pound Beams. If 10 by 10-in beams [...] placed one on top of [the] other, and the upper loaded at the middle, the beams would act as two separate beams (Fig. 1) [...] their combined strength would be no greater than if the two beams were pl[aced] side by side. If, however, the two beams can be joined so that the fibe[rs of] the lower beam will be extended as much as would be the case in a si[ngle] beam of the same depth, or, in other words so that the two beams will [not] slip on each other, the COMPOUND BEAM will have four times the strengt[h of] the SINGLE BEAM.

Tests of Compound Beams. Various attempts have been made to [...] beams thus placed so as to prevent the two parts slipping on each other.

ring the years 1896–7, Edgar Kidwell, of the Michigan College of Mines, ade an extended series of tests of the efficiency of COMPOUND BEAMS of differ-t patterns. From these tests much valuable data was obtained. A full cription of the tests, accompanied by the conclusions of the author, and the s and data for proportioning the bolts and keys, of KEYED BEAMS, is pub-ed in the Trans. Am. Soc. M. E., vol. 27.

Simple Form of Compound Beam. A form of COMPOUND BEAM, some-es used in American building-construction, is shown in Fig. 2, diagonal rds in opposite directions being nailed to each side of the two timbers to vent their slipping on each other. T. M. Clark, in his Building Superin-dence, advocates this as one of the best forms of compound beams, and

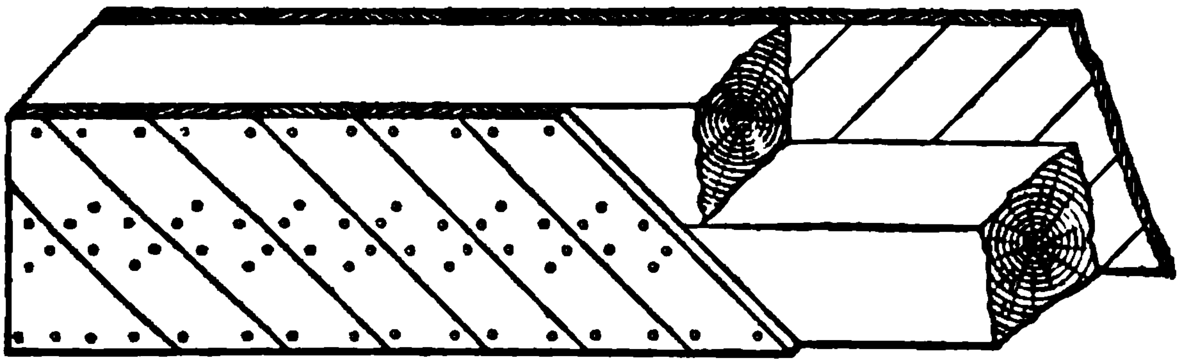

Fig. 2. Simple Form of Compound Wooden Beam

es its EFFICIENCY at about 95% of that of a solid beam of the same depth. fessor Kidwell made nine tests of this type of beam. In six of the beams ratio of span to depth was as 12 to 1, and in three of the beams, as 24 to 1. shorter beams gave an average EFFICIENCY, without much variation, of %, and the longer beams an EFFICIENCY of 80.7%.

It was found that the beams failed by the splitting of the diagonal pieces or drawing of the nails; "in every case, long before the beam broke, the struts open or the nails were partly drawn out or bent over in the wood, thereby itting the component beams to slide on each other." When built with onal boards, 1¼ in thick, nailed with tenpenny nails, as in Fig. 2, the KING STRENGTH of such a beam may be taken at 65% of the strength of

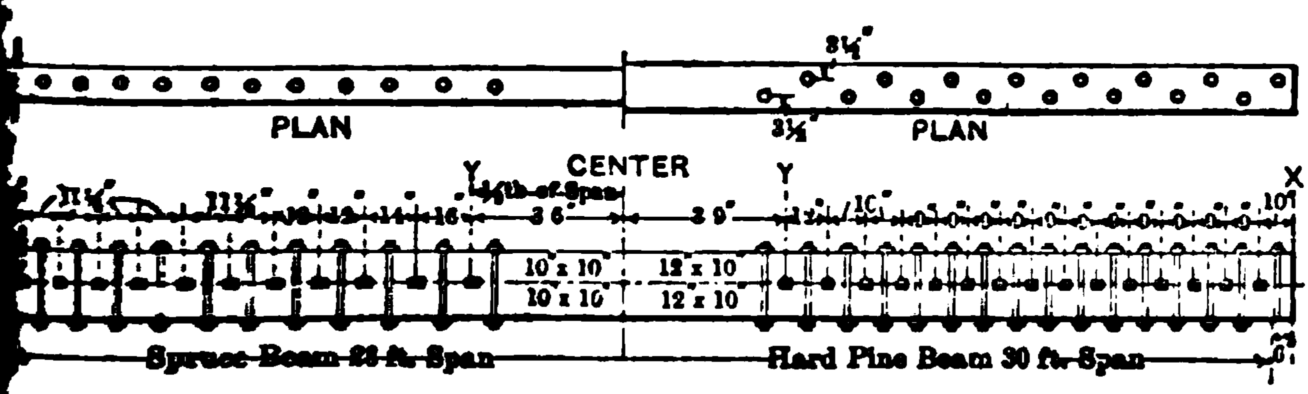

Fig. 3. Compound Keyed and Bolted Wooden Beams

d beam of the same depth and of a breadth equal to the breadth of the ers. The DEFLECTION of the beam, however, will be about double that of d beam of the same size, and on that account this type of beam is not recommended for supporting floors with plastered ceilings or for carrying ered partitions.

eyed Beams. Professor Kidwell tested, also, several types of KEYED , and found that a compound beam keyed and bolted together, as shown g. 3, is the most efficient form that it is practical to build.

It was found that with oak keys it was possible to obtain an EFFICIENCY spruce beams of 95%, while the DEFLECTION varied from 20 to 25% more t would be expected in a solid beam.

Cast-Iron Keys. By using CAST-IRON KEYS the deflection was found t but little, if any, greater than for a solid beam.

Shape of Keys. The keys must be wedge-shaped, as shown in Fig. 4 that they can be driven tightly against the end-wood.

Efficiency of Keyed Beams. Professor Kidwell recommends that ordinary purposes an EFFICIENCY of 75% be allowed when oak keys are and of 80% when the keys are of cast iron. The width of an oak key sh be twice its height. Numerous small keys closely spaced gave better re than fewer large keys. In his report, Professor Kidwell gives formulas, for the number and spacing of the keys.

Keys, Bolts and Washers for Compound Beams. As compound be when used, are generally built up of 8, 10, 12 or 14-in timbers, Mr. Kic some years ago, prepared a table giving the sizes of keys, the number requ on each side of the middle of the span, their minimum spacing and the siz the bolts and washers to be used for such beams of from 20 to 36-ft sp He noted that the MAXIMUM SAFE LOADS for such beams should be 75% o loads computed by Formula (10), page 630, for a beam supported at both e and loaded with a uniformly distributed load.

Table I. Keys, Bolts and Washers for Compound, Keyed Wooden Bea

Size of beams	Size of keys	Bolts	Washers	Number of keys each si of center line			
				White pine	Spruce	Doug-las fir	L[illegible]
16-in beams	1½ by 3 -in oak keys	¾-in	3 -in	7	8	11	
20-in beams	1½ by 3 -in oak keys	¾-in	3 -in	9	11	13	
24-in beams	2 by 4 -in oak keys	⅞-in	3½-in	8	9	12	
28-in beams	2¼ by 4½-in oak keys	⅞-in	3½-in	9	10	12	

Size of keys	Bolts	Washers	Minimum spacing of ke			
1½ by 3 -in oak keys	¾-in	3-in	11¼-in	11¼-in	9 -in	9
2 by 4 -in oak keys	⅞-in	3-in	15 -in	15 -in	11½-in	11
2¼ by 4½-in oak keys	⅞-in	3-in	17 -in	17 -in	13 -in	13

The Breadth or Thickness of Compound Beams should be not less two-fifths of the depth.

The Number of Keys required is not affected by the length or bread the beam, if the beam is figured for the full safe load.

In Spacing the Keys (Figs. 3 and 4) they should not be closer tha minimum spacing given in Table I. For beams loaded at the middle, the ing of the keys should be uniform from X to Y, Fig. 3, Y being one-eight span from the center line. If the distance between the keys, center to

works out less than the minimum spacing, the safe load should be cor-ndingly reduced or the thickness of the beam increased.

Beams Uniformly Loaded, the first four or five keys from the end ld be spaced for minimum spacing, and the spacing of the remaining keys ased toward the point *Y*. When the ratio of depth to span is greater than 16, the inner key may be a little more than one-eighth the span from the er line, for distributed loads. Fig. 3 shows the proper spacing for a 20-in e beam of 28-ft span and for a long-leaf yellow pine beam of 30-ft span; the tabulation below gives the proper spacing of keys for spruce beams of

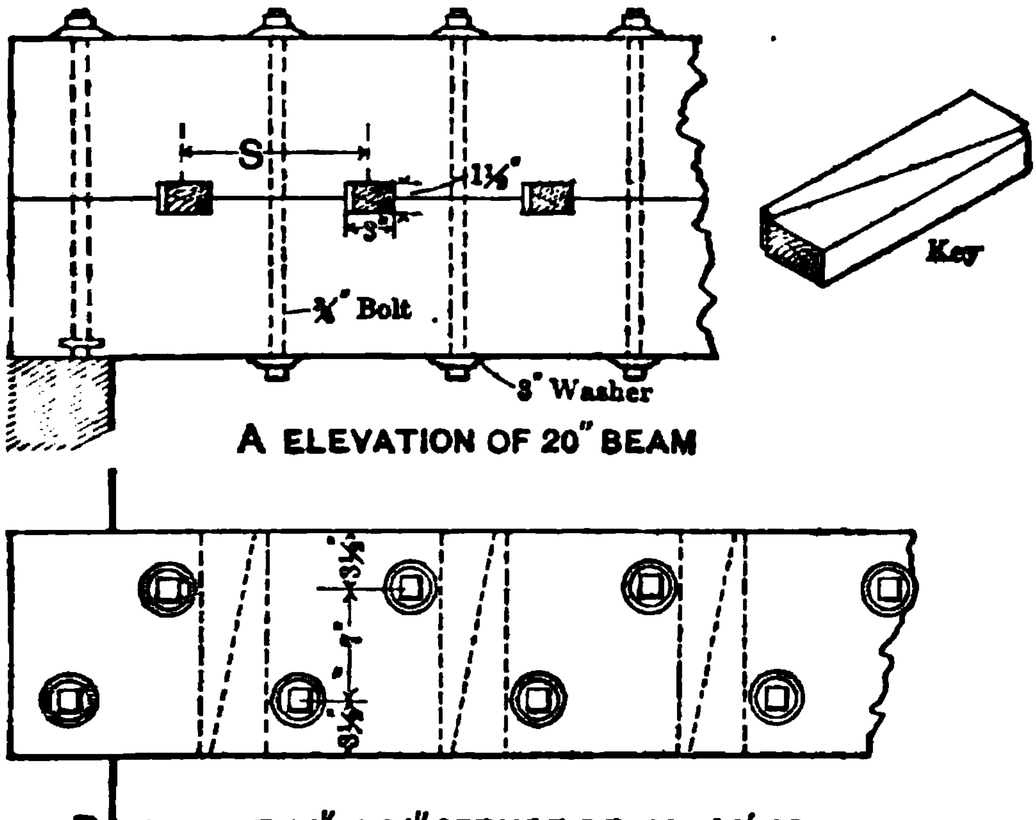

Fig. 4. Details of Keyed and Bolted Wooden Beam

r spans, figured from the end of the beam in each case. For other woods spans the spacing should be made as near like these as the fixed condi- will permit. Four examples of spacing are given below. The sizes of and washers to be used are given in Table I. If the beam is not over wide, the bolts may be arranged as for the spruce beam (Fig. 3); if 12 in or over, the bolts should be staggered as shown for the hard-pine beam. very wide beam the bolts might be spaced as in detail *B*, Fig. 4.

cing of keys in inches for spruce beams, commencing at end, for uniformly buted loads:

in spruce beam, 32-ft span,	10,	12,	12,	16,	19, 24, 32
in spruce beam, 32-ft span,	10,	11½,	11½,	11½,	12, 12, 12, 13, 15, 18, 24
in spruce beam, 36-ft span,	13,	15,	15,	15,	15, 16, 18, 20, 30
in spruce beam, 36-ft span,	15,	17,	17,	17,	17, 17, 17, 17, 17, 17

2. Flitched Beams or Flitch-Plate Girders

ch-Plate Beams (Fig. 5) were at one time much used, but with the t prices of steel it is cheaper and better to use steel beams.

following explanation and formulas are given, however, for the benefit e who might have occasion to use a beam of this kind. It has been in practice that the thickness of the wood should be sixteen times the ss of the steel. As the steel is so much STIFFER than the wood, we must

proportion the load on the wood so that the latter will bend as much steel plate bends: otherwise the whole load might be thrown on the steel The MODULUS OF ELASTICITY of steel is about twenty times that of lo yellow pine; so that a beam of this wood, 1 in wide, will bend twenty as much as a plate of steel of the size and under the same load. if we want this beam to bend much as the steel plate, we mus only one-twentieth the load on the wooden beam is sixteen tim thick as the steel plate, we should put sixteen-twentieths of its safe load or, what amounts to the same thing, use a constant only four-fifths strength of the wood.

Fig. 5. Flitch-plate Girder

Formulas for Flitch-Plate Girders. On this basis the following for have been derived for the strength of FLITCH-PLATE GIRDERS, in which the ness of the wood is sixteen times the breadth of the steel, approximately:

Let d = depth of beam in inches
b = total thickness of wood in inches
l = clear span in feet
t = thickness of steel plate in inches

$$A'^{*} = \begin{cases} 53.6 \text{ for long-leaf yellow pine} \\ 45 \text{ for Douglas fir} \\ 31 \text{ for spruce} \end{cases}$$

P = total load at middle in pounds
W = distributed load in pounds

Then, for beams supported at both ends,

$$\text{Safe load at middle in pounds} = \frac{d^2}{l}(A'b + 889\,t)$$

$$\text{Safe distributed load in pounds} = \frac{2\,d^2}{l}(A'b + 889\,t)$$

$$\text{For distributed load,} \qquad d = \sqrt{\frac{Wl}{2\,A'b + 1778\,t}}$$

$$\text{For load at middle,} \qquad d = \sqrt{\frac{Pl}{A'b + 889\,t}}$$

The bolts should be ¾ in in diameter, and spaced 2 ft on centers. end should have two bolts, as in Fig. 5.

Example. What is the safe load, uniformly distributed, for a girder com of three 4 by 14-in Douglas-fir timbers and two ⅜ by 14-in flitch-plates, span of 25 ft?

Solution. By Formula (2),

$$\text{Safe load} = \frac{2 \times 196}{25}(45 \times 12 + 889 \times 3/4) = 18\,922 \text{ lb}$$

3. Trussed Beams and Girders

Use of Trussed Beams and Girders. Whenever we wish to supp floor upon girders having a span of more than 30 ft, we must use a TR GIRDER, a riveted STEEL-PLATE GIRDER, or two or more STEEL BEAMS.

* For commercially seasoned timber and for ideal conditions these values may i about 30%.

me circumstances and in some parts of the country it may be cheaper or re convenient to use a large wooden girder, and truss it, as in Figs. 6, 7, 8 or 9.

Depth of Trussed Girder. For all these forms it is desirable to give the ders as much depth as the conditions allow; as, the deeper the girder, the aller the stresses in the pieces.

In the Single-Strut Trussed Girder, we either have two beams, and one d which runs up between them at the ends, or three beams, and two rods ning up between the beams in the same way. The beams should be in one ntinuous length for the whole span, if they can be obtained in that length. e requisite dimensions of the tie-rod, struts and beams, in any given case, st be determined by first finding the stresses developed in these pieces, and en the areas of cross-sections required to resist these stresses.

For a Single-Strut Truss (Fig. 6), the stresses in the pieces may be deter-ned by the following formulas:

r a Distributed Load *W* Over the Whole Girder (Fig. 6)

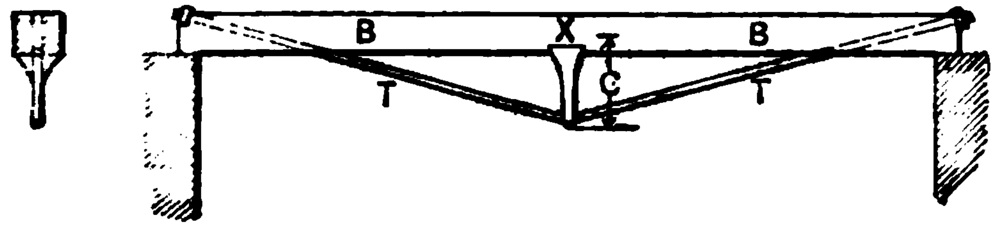

Fig. 6. Trussed Wooden Girder. One Vertical Strut

$$\text{Tension in } T = \frac{W}{2} \times \frac{\text{length of } T}{\text{length of } C} \qquad (5)$$

$$\text{Compression in } C = \tfrac{5}{8} W. \quad \text{(See Note.)} \qquad (6)$$

$$\text{Compression in } B = \frac{W}{2} \times \frac{\text{length of } B}{\text{length of } C} \qquad (7)$$

te. When the beam B is in one piece, the full length of span. If B is ted over the strut then compression in C or tension in $R = \tfrac{1}{2} W$.

r a Concentrated Load *P* Over *C* (Fig. 6)

$$\text{Tension in } T = \frac{P}{2} \times \frac{\text{length of } T}{\text{length of } C} \qquad (8)$$

$$\text{Compression in } C = P$$

$$\text{Compression in } B = \frac{P}{2} \times \frac{\text{length of } B}{\text{length of } C} \qquad (9)$$

r a Girder Trussed as in (Fig. 7), Under a Distributed Load *W* Over the le Girder

$$\text{Compression in } S = \frac{W}{2} \times \frac{\text{length of } S}{\text{length of } R} \qquad (10)$$

$$\text{Tension in } R = \tfrac{5}{8} W. \quad \text{(See Note.)}$$

$$\text{Tension in } B = \frac{W}{2} \times \frac{\text{length of } B}{\text{length of } R} \qquad (11)$$

te. When the beam B is in one piece, the full length of span. If B is d over the strut then compression in C or tension in $R = \tfrac{1}{2} W$.

For a Concentrated Load, P at the Middle (Fig. 7)

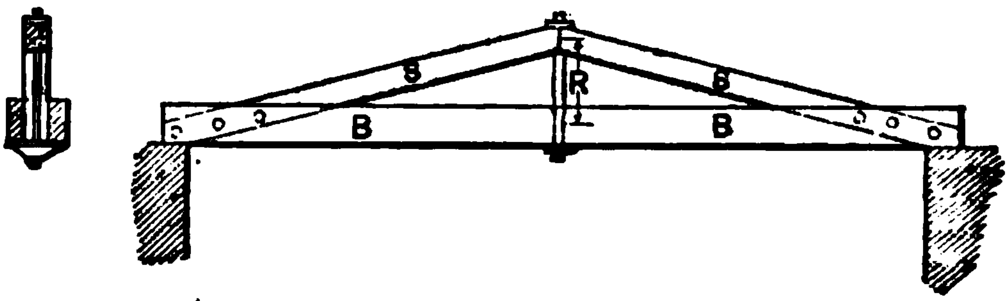

Fig. 7. Trussed Wooden Girder. One Vertical Tie

$$\text{Compression in } S = \frac{P}{2} \times \frac{\text{length of } S}{\text{length of } R}$$

$$\text{Tension in } R = P$$

$$\text{Tension in } B = \frac{P}{2} \times \frac{\text{length of } B}{\text{length of } R}$$

For a Double-Strut Trussed Beam (Fig. 8) with a Distributed Load W the Whole Girder (Beam B Divided into Three Equal Spans)

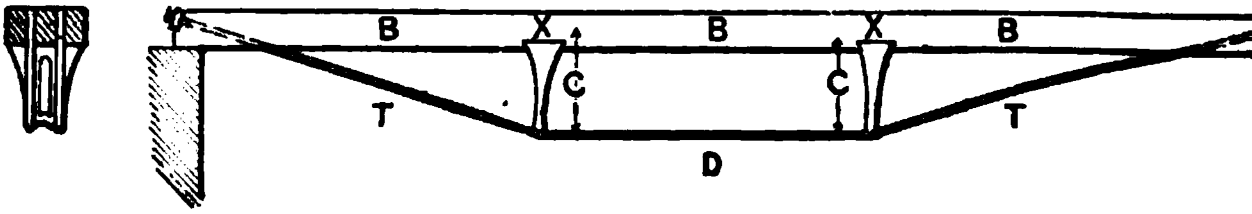

Fig. 8. Trussed Wooden Girder. Two Vertical Struts

$$\text{Tension in } T = \frac{W}{3} \times \frac{\text{length of } T}{\text{length of } C}$$

$$\text{Compression in } C = \frac{W}{3}$$

$$\text{Compression in } B \text{ or tension in } D = \frac{W}{3} \times \frac{\text{length of } B}{\text{length of } C}$$

For a Concentrated Load P Over Each of the Struts C (Fig. 8)

$$\text{Tension in } T = P \times \frac{\text{length of } T}{\text{length of } C}$$

$$\text{Compression in } C = P$$

$$\text{Compression in } B \text{ or tension in } D = P \times \frac{\text{length of } B}{\text{length of } C}$$

For a Girder Trussed as in Fig. 9, and Under a Distributed Load W the Whole Girder (Beam B Divided into Three Equal Spans)

$$\text{Compression in } S = \frac{W}{3} \times \frac{\text{length of } S}{\text{length of } R}$$

$$\text{Tension in } R = \frac{W}{3}$$

$$\text{Tension in } B \text{ or compression in } D = \frac{W}{3} \times \frac{\text{length of } B}{\text{length of } R}$$

For Concentrated Loads P Applied at Joints 2 and 3 (Fig. 9)

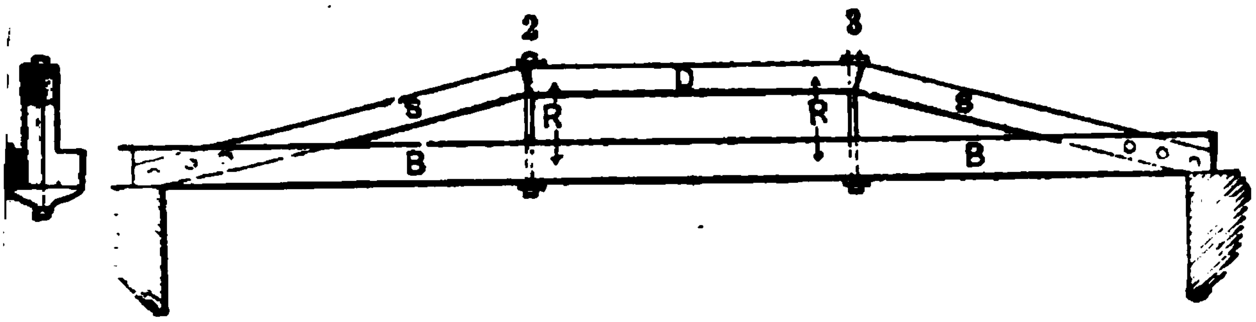

Fig. 9. Trussed Wooden Girder. Two Vertical Ties

$$\text{Compression in } S = P \times \frac{\text{length of } S}{\text{length of } R} \tag{20}$$

$$\text{Tension in } R \quad = P$$

$$\text{Tension in } B \text{ or compression in } D = P \times \frac{\text{length of } B}{\text{length of } R} \tag{21}$$

Trusses constructed as shown in Figs. 8 and 9 should be divided so that the rods R, or the struts C, will divide the lengths of the girder into three equal or nearly equal parts. The lengths of the pieces T, C, B, R, S, etc. should be measured ON THE AXIAL LINES of the pieces. Thus, the length of R should be measured from the CENTER LINE OR AXIS of the tie-beam B to the CENTER LINE or axis of the strut D; and the length of C should be measured from the AXIS of the rod to the AXIS of the strut-beam B.

After determining the stresses in the pieces by these formulas, we may compute the areas of the cross-sections by the following rules:

$$\text{Area of cross-section of a short strut} = \frac{\text{compression in strut}}{S_c} \tag{22}$$

in which S_c for cast iron may be taken at from 13 000 or 14 000 lb per sq in, and for wood as given in Table XVI, page 647.

The size of the long strut D (Fig. 9) should be determined by means of Tables 451 and 452 for wooden columns, Chapter XIV.

The diameters of the tie-rods may be obtained from Table II, page 388.

For the beam B (Figs. 8 and 9) when the load is distributed, we must compute the necessary area of cross-section as a STRUT (Fig. 8) or a TIE (Fig. 9), and also the area of its cross-section, as a BEAM, required to support its load, and use a beam with a section equal to the sum of the two sections thus obtained.

$$\left.\begin{array}{c}\text{Area of cross-section of } B \text{ to resist}\\ \text{tension or compression}\end{array}\right\} = \frac{\text{tension}}{S_t} \text{ or } \frac{\text{compression}}{S_c} \tag{23}$$

For the trusses shown in Figs. 6 and 7, with distributed loads,

$$\text{Breadth of } B \text{ (as a beam)} = \frac{W \times l}{4 \times d^2 \times A} \tag{24}$$

For the trusses shown in Figs. 8 and 9, with distributed loads,

$$\text{Breadth of } B \text{ (as a beam)} = \frac{W \times l}{6 \times d^2 \times A} \tag{25}$$

(Compare Equation (24) and (25) with Equation (11), page 630.)

W denotes the total distributed load in pounds on the girder, and l the length in feet of one section of the beam. When the loads are concentrated over the struts C (Fig. 8) or at the joints R (Fig. 9) then there will be no TRANSVERSE

STRESS on the beams B, and they need be proportioned for the COMPRES or TENSILE STRESS, only, as the case may be.

In Formulas (23), (24) and (25), for S_c and S_t, substitute the values safe unit stresses for compression, Table XVI, page 647, and for tension, T II, page 388, and for A substitute the values recommended in Tables II XVI, pages 628 and 647.

Illustrative Examples. To illustrate the method of computing the di sions of the different parts of girders of this kind, two examples are given.

Example 1. It is required to design a trussed girder of the form show Fig. 6, for a span of 30 ft. The girders are to be 12 ft on centers, and a carry a floor loaded with 100 lb per sq ft. The girder consists of three s beams B, side by side, and two rods. We can allow the rod T to come two below the beams B, and we will assume that the depth of the beams B be 12 in; then the length of C, measured from the center line of the beam, be 30 in. The length of B is 15 ft, and by computation, or by scaling, we the length of T to be 15 ft 2½ in.

Solution. The total load on the girder equals 100 lb multiplied by the multiplied by the distance of the girders on centers, or, $100 \times 30 \times 12 = 36$ 0
From Formula (5),

$$\text{Tension in } T = \frac{36\,000}{2} \times \frac{182\tfrac{1}{2}\text{ in}}{30\text{ in}} = 109\,500\text{ lb}$$

or 54 750 lb on each of the two rods. For such a large stress it is best to the ends of the rods, and allowing 16 000 lb per sq in for steel rods, we find Table II, Chapter XI, that we must use two 2⅛-in steel rods.

The strut-beam we will make of long-leaf yellow pine. From Formula (find the compressive stress in $B = (36\,000/2) \times (180/30) = 108\,000$ lb. As w to use three beams side by side, there will be 36 000 lb compression in each b

To resist the compression there is required an area of 36 000/1 000 or 36 s which is equal to 3 by 12 in.

From Formula (24) we find the total breadth required to resist the trans stress $= \dfrac{36\,000 \times 15}{4 \times 144 \times 67} = 14$ in; or each beam must be 4⅔ by 12 in in secti resist the transverse stress, and 3 by 12 in to resist the compressive s Consequently each beam must be 7⅔ by 12 in in cross-section.

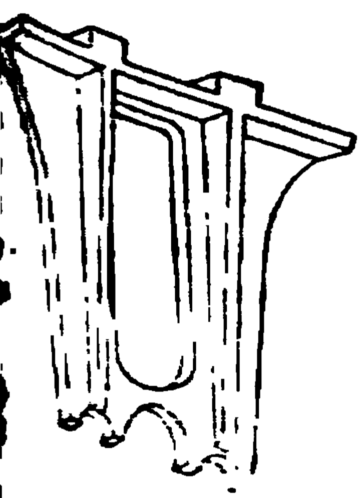
As this would make the girder very wide, 27¼ in, we will use beams deep, increasing the depth of the girder 1 in, so that the height on center still be 30 in.

The area required to resist the compressive stress will be the same as b 36 in, but as the beam is 14 in deep the breadth will be only 2.57 in.

The total breadth to resist the transverse stress will be $\dfrac{36\,000 \times 15}{4 \times 196 \times 67} = 10.$ or 3.43 in for each beam. The total breadth for each beam will therefo 6 in. A beam with a cross-section of 6 by 14 in will meet the requiren The total width of the girder will then be 22¼ in. The load on $C =$ ⅝ 22 500 lb, or 11 250 lb over each rod. The theoretical sectional area in s inches necessary to resist this load = 11 250/13 000 for cast iron and 11 250/ for oak. As the struts must be the full width of the girder, however, i be necessary to make the sectional area much greater than the theoretic quirements. If made of cast iron the strut should be of the shape sho Fig. 10, and if of oak, of the shape shown in Fig. 11. The cast-iron stru be the best, but an oak strut will answer.

mple 2. It is required to support a floor over a lecture-room 40 ft wide, neans of trussed girders; and as the room above is to be used for electrical poses, it is desired to have a truss with very little iron in it. It is decided, efore, to use a truss such as is shown in Fig. 9.

lution. Where the girders rest on the wall, there will be brick pilasters ing a projection of 6 in, which will make the span of the truss 39 ft, and rods *RR* will be placed so as to divide the tie- into three equal spans of 13 ft each. The tie-beam *B* will consist of two long-leaf yellow pine beams, with the struts *S* coming between them. There are two rods, instead of one, at *RR*, coming down on each side of the struts *S*, and passing through iron castings below the beams *B*, and forming supports for them. The height of the truss from center to center of timbers must be limited to 18 in. The trusses are 8 ft on centers.



. 10. Cast-iron Strut for Two Tie-rods

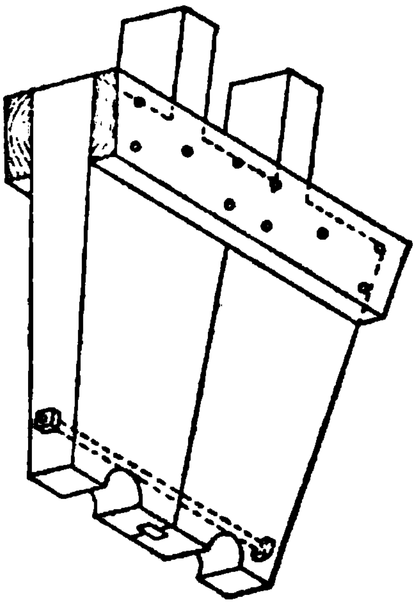


Fig. 11. Wooden Strut for Two Tie-rods

he total floor-area supported by one girder is 8 by 39 ft, or 312 sq ft. The iest load to which the floor will be subjected is the weight of the people the room, for which 75 lb per sq ft is an ample allowance; and the weight he floor itself is about 100 lb per sq ft. This makes the total weight liable ome on one girder 31 200 lb.

$$\text{Compression in } S\text{, from Formula (18)} = \frac{W}{3} \times \frac{157 \text{ in}}{18 \text{ in}} = 90\,700 \text{ lb}$$

$$\text{Tension in one pair of rods} = \frac{W}{3} = 10\,400 \text{ lb}$$

$$\text{Tension in } B \text{ or compression in } D = \frac{W}{3} \times \frac{156 \text{ in}}{18 \text{ in}} = 90\,130 \text{ lb}$$

the unsupported length of *D* is greater than that of *S*, a beam that will t the compression in *D* will be ample for *S*. We find from Table II, Chap. XIV, that it will require a post 10 by 12 in in cross-section to resist the com- sion in *D*, which is 13 ft in length. The tension in each rod is only 5 200 lb; as the rods must support a larger washer at the bottom, they are made in diameter, not upset. The tension in each of the beams *B* is 45 065 lb. divided by 1 200, the safe unit tensional stress for long-leaf yellow pine 37.6 sq in, or about 2¾ by 14 in.

he total breadth of the tie-beam to resist the transverse load is found from nula (25). Assuming 14 in for the depth of *B*

$$\text{Breadth of } B = \frac{31\,200 \times 13}{6 \times 196 \times 67} = 5.15 \text{ in, or about } 2\tfrac{1}{2} \text{ in for each beam}$$

he breadth of each tie-beam must therefore be 2¾ in + 2½ in = 5¼ in. ce the tie-beams must be 5 by 14 in in section. The girder, therefore, must built with 10 by 14-in strut-beams and two 5 by 14-in tie-beams, each 42 ft . The 1-in rods may be cut ½ in into the strut-beams, and ½ in into the tie-

beams, so that the latter will come close against the struts S. The thrus the strut S is equal to its compressive stress, and a connection between the beams and the struts must be designed that will resist this thrust, which in case is 90 700 lb. As the inclination of the strut is very slight, there is an room for bolts. It is best to use bolts which are at least 1½ in in diame As they are in double shear, the resistance to shearing of one bolt is 35 34 (See Table IX, page 431.) Steel bolts are used.

The bearing area of a 1½-in bolt in a timber 10 in wide is 15 in. For bearing resistance of long-leaf yellow pine, we may allow 1 400 lb per s (Table XVI, page 647), which will give 21 000 lb as the bearing resistanc one 1½-in steel bolt. As the force to be resisted is 90 700 lb, it will req five 1½-in steel bolts to sustain this bearing pressure, the resistance to shea being greater than this stress.

The number of bolts required to resist the bending moment must now determined. The total bending moment to be resisted (see page 434, Cl ter XII) = 90 700 times the distance, in inches, between the centers of the beams divided by 12, or $90\,700 \times {}^{15}\!/_{12} = 113\,375$ in-lb.

From Table IX, page 431, we find that the maximum bending mom at a fiber-stress of 20 000 lb per sq in, for a 1½-in steel bolt is 6 630 i Hence it will require seventeen 1½-in bolts to resist the thrust in S witl bending the bolts. As it is impracticable to put in so many bolts, larger must be used. For a 2½-in steel bolt, the maximum bending momer 30 700 in-lb (Table IX, page 431), and four times this is 122 800 i hence four 2½-in steel bolts will be sufficient to resist the bending stress, also the shearing and bearing-stresses. It will be seen from this example it is much more difficult and expensive to make satisfactory end-joint girders trussed as in Figs. 7 and 9 than it is for the single and double-s trusses like those shown in Figs. 6 and 8. The latter forms are to be prefe when the conditions will admit of their use.

These four cases of TRUSSED GIRDERS are but special examples of tru The stresses in them may also be determined by the methods explaine Chapter XXVII; and where the divisions of the girder cannot be made form, the stresses should be computed by the general methods there explai

CHAPTER XVIII

STIFFNESS AND DEFLECTION OF BEAMS

BY
CHARLES P. WARREN
LATE ASSISTANT PROFESSOR OF ARCHITECTURE, COLUMBIA UNIVERSITY

1. General Principles of the Deflection of Beams*

Strength and Stiffness. In many structures it is necessary that beams and girders shall be not only STRONG enough but STIFF enough; that is, not only must RUPTURE be prevented, but the beams must not BEND so much as to appear unsightly, or to crack the ceiling. Therefore, in many cases, DEFLECTION, rather than absolute STRENGTH, may become the governing consideration in determining the size of a beam. Unfortunately, there is no method at present of combining the two calculations for STRENGTH and for STIFFNESS in one. A beam properly proportioned for STRENGTH will not bend enough to stress the fibers beyond the ELASTIC LIMIT, but it may in some cases bend more than a due regard for appearances will justify. The distance that a beam bends under a given load is called its DEFLECTION, and its resistance to deflection is called its STIFFNESS.

A General Formula for the Maximum Deflection of any beam under a concentrated or uniformly distributed load not stressed beyond the ELASTIC LIMIT is:

$$\text{Deflection in inches} = \frac{\text{load in pounds} \times \text{cube of span in inches} \times c}{\text{modulus of elasticity} \times \text{moment of inertia}} \qquad (1)$$

The values of c are as follows:

For beam supported at both ends, loaded at the middle......	0.021
For beam supported at both ends, uniformly loaded.........	0.013
For cantilever beam, loaded at free end....................	0.333
For cantilever beam, uniformly loaded.....................	0.125

Deflection of Beam with Rectangular Section. By making the proper substitutions in Formula (1), the following formula for a RECTANGULAR beam SUPPORTED AT BOTH ENDS and LOADED AT THE MIDDLE may be derived:

$$\text{Deflection in inches} = \frac{\text{load in pounds} \times \text{cube of span in feet} \times 1\,728}{4 \times \text{breadth} \times \text{cube of depth} \times E} \qquad (2)$$

Modulus of Elasticity. From this formula the value of the MODULUS OF ELASTICITY, E, for different materials, has been calculated by accurately measuring the actual deflection of known beams under given loads applied at the middle and then substituting these known quantities in Formula (2).

Simple Formula for Deflection. Formula (2) may be simplified somewhat by representing $1\,728/4E$ by $1/F$, which gives the formula

$$\text{Deflection in inches} = \frac{W \times l^3}{b \times d^3 \times F\dagger} \qquad (3)$$

For a DISTRIBUTED LOAD the deflection will be five-eighths of this.

* See also, in Chapter XVI, formula on page 636 and Table XVI, page 647.

† The constant F corresponds to Hatfield's F, in his treatise on "Transverse Strains."

To Find the Load at the Middle that will cause a GIVEN DEFLECTI transpose Formula (2) so that the load becomes the left-hand member of equation. Thus:

$$\text{Load at middle in pounds} = \frac{4 \times \text{breadth} \times \text{cube of depth} \times \text{deflection in in} \times E}{\text{cube of span} \times 1\,728}$$

Limit of Deflection. In order that this formula may be of use in de mining the maximum load which may be placed upon a beam, the LIMIT OF DEFLECTION must in some way be fixed. This is generally done by making certain proportion of the span.

Allowable Deflection of Floor-Beams. Tredgold and other authori state that if a floor-beam deflects more than ONE-FORTIETH OF AN INCH EVERY FOOT OF SPAN, it is liable to crack the ceiling on the under side; and he this is the limit which is often set for the deflection of beams in first-c buildings.

Formulas for Deflection of Floor-Beams. If the length in feet divi by 40 is substituted for the deflection in inches, Formula (4) becomes

$$\text{Load at the middle} = \frac{\text{breadth} \times \text{cube of depth} \times e}{\text{square of span in feet}}$$

in which
$$e = \frac{E}{17\,280}$$

Most engineers and architects, however, think that ONE-THIRTIETH OF INCH PER FOOT OF SPAN, that is, 1/360 of the span, is not too much to allow the deflection of floor-beams, as a floor is seldom subjected to its full estim load, and then only for a short time.

Table I. Values of Constants for Stiffness or Deflection on Beams*

Material	E †	$F = \frac{E}{432}$	$e = \frac{E}{17\,280}$	$e_1 = \frac{E}{12\,9}$
Cast iron	15 000 000	34 722	862	1 157
Wrought iron	26 000 000	60 000	1 500	2 000
Steel	29 000 000	67 130	1 678	2 238
Ash	1 482 000	3 430	87	114
California redwood	700 000	1 620	40	54
Cedar	700 000	1 620	40	54
Chestnut	900 000	2 080	52	69
Cypress	900 000	2 080	52	69
Douglas fir	1 500 000	3 472	87	116
Hemlock	900 000	2 080	52	69
Long-leaf yellow pine	1 500 000	3 472	87	116
Maple	1 902 000	4 400	110	146
Norway pine	1 100 000	2 546	64	85
Short-leaf yellow pine	1 200 000	2 777	69	92
Spruce	1 200 000	2 777	69	92
White oak	1 500 000	3 472	87	116
White pine	1 000 000	2 315	58	77

E = modulus of elasticity, pounds per square inch; seasoned timber;
F = constant for deflection of beam, supported at both ends, loaded at middl
e = constant, allowing a deflection of one-fortieth of an inch per foot of span
e_1 = constant, allowing a deflection of one-thirtieth of an inch per foot of spa

* See, also, in Chapter XVI formula on page 636, and Table XVI, page 647.
† See Notes, page 637, regarding reductions in value for E, for unseasoned timb

If this ratio is adopted, the CONSTANT FOR DEFLECTION becomes

$$e_1 = \frac{E}{12\,960}$$

Constants for Stiffness or Deflection of Beams. In either of the above cases it is evident that the values used for E, F, e, or e_1, should be derived from tests on timbers of the same size and quality as those to be used. The values for the various woods given in the preceding table have been adopted by the editors after careful comparison with the results of numerous tests on large timbers and with values given by different authorities. The editors believe that they are perfectly reliable for first-class, seasoned, merchantable timber.

2. Formulas for Loads, Based Upon the Stiffness of Beams

Safe Loads for Limited Deflections for Rectangular Beams. Knowing the deflection caused by a load concentrated at the middle of a beam, and the RATIO OF OTHER DEFLECTIONS, caused by different modes of loading and supporting, formulas for Cases I to VIII, Figs. 1 to 8, considered under the strength of RECTANGULAR BEAMS (Chapter XVI), can be easily deduced. These cases, arranged in a different order, are:

For Beams Supported at Both Ends*

Load at the middle

$$\text{Safe load} = \frac{\text{breadth} \times \text{cube of depth} \times e_1}{\text{square of span}} \qquad (6)$$

$$\text{Breadth} = \frac{\text{load} \times \text{square of span}}{\text{cube of depth} \times e_1} \qquad (7)$$

Load at a point other than at the middle, ***m*** **and** ***n*** **being the segments into which the beam is divided**

$$\text{Safe load} = \frac{\text{breadth} \times \text{cube of depth} \times \text{square of span} \times e_1}{16 \times m^2 \times n^2} \qquad (8)$$

$$\text{Breadth} = \frac{\text{load} \times m^2 \times n^2 \times 16}{\text{cube of depth} \times \text{square of span} \times e_1} \qquad (9)$$

Load uniformly distributed

$$\text{Safe load} = \frac{8 \times \text{breadth} \times \text{cube of depth} \times e_1}{5 \times \text{square of span}} \qquad (10)\dagger$$

$$\text{Breadth} = \frac{5 \times \text{load} \times \text{square of span}}{8 \times \text{cube of depth} \times e_1} \qquad (11)$$

Inclined beam, loaded at the middle‡

$$\text{Safe load} = \frac{\text{breadth} \times \text{cube of depth} \times e_1}{\text{span} \times \text{horizontal distance between supports}} \qquad (12)$$

$$\text{Breadth} = \frac{\text{load} \times \text{span} \times \text{horizontal distance between supports}}{\text{cube of depth} \times e_1} \qquad (13)$$

* In Formulas (6) to (17) the breadth and depth are to be taken in inches, and the length or span in feet. The load is always in pounds.
The values given in either of the last two columns of Table I may be used for e or e_1, according to the degree of stiffness desired, but the values e_1 in the last column are ample under ordinary conditions.

† See, also, formula in Chapter XVI, page 636.

‡ Tredgold's Elements of Carpentry, page 65.

For Beams Fixed at One End, or Cantilever Beams

Load at the free end

$$\text{Safe load} = \frac{\text{breadth} \times \text{cube of depth} \times e_1}{16 \times \text{square of span}}$$

or,

$$\text{Breadth} = \frac{16 \times \text{load} \times \text{square of span}}{\text{cube of depth} \times e_1}$$

Load uniformly distributed

$$\text{Safe load} = \frac{\text{breadth} \times \text{cube of depth} \times e_1}{6 \times \text{square of span}}$$

or,

$$\text{Breadth} = \frac{6 \times \text{load} \times \text{square of span}}{\text{cube of depth} \times e_1}$$

Note. When the span in feet is less than the depth in inches, the be should not be calculated by the formulas for STIFFNESS, but by those for HO ZONTAL SHEAR. (See Chapter XVI, page 635.)

3. Relative Stiffness of Beams

Beam supported at both ends and loaded at the middle.........	1
Beam supported at both ends and uniformly loaded.............	8/
Beam fixed or restrained at both ends and loaded at the middle...	4
Beam fixed or restrained at both ends and uniformly loaded.....	8
Cantilever beam loaded at the free end........................	1/1
Cantilever beam uniformly loaded..............................	1/6

The Stiffest Rectangular Beam containing a given amount of materia that in which the ratio of depth to breadth is as 10 is to 6; hence, in desigr beams, the depth and breadth should be made to approach as near this rati is practicable.

Example 1. What is the greatest distributed load that an 8 by 10 in wh pine girder, 20 ft in span, will support, without deflecting at the center m than one-thirtieth of an inch per foot of span?

Solution. This girder comes under the case of a beam supported at b ends and loaded with a uniformly distributed load, and hence should be ca lated by Formula (10). Substituting the given dimensions in Formula (

$$\text{Safe load} = \frac{8 \times 8 \times 1\,000 \times 77}{5 \times 400} = 2\,464 \text{ lb}$$

Example 2. What should be the dimensions of a long-leaf yellow-pine be 10 ft in span, to support a concentrated load of 4 250 lb at the middle with deflecting more than one-third of an inch at the center?

Solution. A deflection of one-third of an inch in a span of 10 ft is in the p portion of one-thirtieth of an inch per foot of span; and as the load is con trated at the middle, Formula (7) should be used, with e_1, the value given in fourth column opposite long-leaf yellow pine.

Formula (7) gives the dimensions of the breadth, but in order to obtain a value for the depth must first be assumed. For such a short span, 10 inc would seem to be a proper depth.

Substituting in Formula (7)

$$\text{Breadth} = \frac{4\,250 \times 100}{1\,000 \times 116} = 3.6 \text{ in}$$

Hence it will be necessary to use a 4 by 10-in beam. As the span of this beam in feet is the same as its depth in inches, it should be tested to see if it meets the requirements for strength also. From Table XII, page 643, it is found that the safe distributed load for a 1 by 10-in beam, 10 ft in span, is 1 333 lb, and for a 4 by 10-in beam the safe load would be four times as much, or 5 332 lb. The load in this example, however, is applied at the middle; hence the safe distributed load must be divided by 2, which gives 2 666 lb for the safe load at the middle. As this is much less than the load to be carried, the size of the beam should be increased to 4 by 16 in. In general it is not safe to use the FORMULAS FOR STIFFNESS when the span in feet does not exceed the depth in inches.

Example 3. What is the largest load that an inclined spruce beam 8 by 12 in in cross-section and 16 ft in length between the supports will carry at the middle, consistent with stiffness, the horizontal distance between the supports being 14 ft?

Solution. Formula (12) is the one to be used in this case. Assuming the limit of deflection at one-thirtieth of an inch per foot of span, the value of e_1 is found opposite spruce in the last column of Table I. Making the proper substitutions,

$$\text{Safe load} = \frac{8 \times 1\,728 \times 92}{16 \times 14} = 5\,678 \text{ lb}$$

4. Cylindrical Beams

Formulas. The formulas for beams with SQUARE CROSS-SECTIONS may be used for beams with CIRCULAR CROSS-SECTIONS, if $1.7 \times e$ is substituted for e. That is, other conditions being equal, a CYLINDRICAL BEAM bends or deflects 1.7 times as much as a beam the cross-section of which is the square circumscribing the circular cross-section of the cylindrical beam.

5. Safe Loads for Wooden Beams for a Given Deflection

Use of Tables and Formulas. Tables VII to XV, inclusive, pages 638 to 646, giving the SAFE LOADS FOR BEAMS, give, also, the maximum loads for beams, 1 in thick, that will cause a DEFLECTION not exceeding 1/360 of the span, that is, 1/30 in per foot of span. Where two loads are given for any span or depth the upper load is calculated for STRENGTH and the lower load for DEFLECTION. Where one load is given the calculation is for strength, as the calculation for deflection in those particular beams would give an excessive load (Example 2). To find the corresponding load for any thickness, multiply the load given in the table by the breadth of the beam in inches. Suppose, for example, that it is required to find the greatest distributed load that an 8 by 10-in white-pine girder, 20 ft in span, will support, without deflecting at the center more than one-thirtieth of an inch per foot of span. Referring to Table VIII, page 639, giving the safe loads in pounds for white-pine beams, two values are found opposite the 20-ft span, 389 and 308, the latter being the safe load for deflection. The safe load, therefore, for an 8 by 10-in girder will be eight times, or $308 \times 8 = 2\,464$ lb, which agrees with the safe load for the same girder calculated for deflection by Formula 10, Example 1.

6. Nominal and Standard Sizes of Wooden Beams

Conversion Factors for Wooden Beams of Standard Size. Table II may be used for beams that measure less than the NOMINAL DIMENSIONS. DRESSED BEAMS, and in many localities floor-joists carried in stock, are more

or less SCANT of the nominal dimensions, and for such joists a reduction in t safe load must be made to correspond to the reduction in size. The DRESS SIZES are generally ¼ in scant up to 4 in in breadth, above which they are ½ scant; while in depth they are all generally ½ in less than the NOMINAL SIZ The safe loads may be obtained by multiplying the safe loads as given Tables VII to XV, pages 638 to 646, by the FACTORS given in the followi table:

Table II. Conversion Factors for Beams of Commercial or Standard Sizes

Cross-sections of beams in inches	Factors	Cross-sections of beams in inches	Factors
1¾×5½	1.47	1¾×11½	1.61
2¾×5½	2.31	2¾×11½	2 53
1¾×6½	1.51	1¾×13½	1 63
2¾×6½	2.51	2¾×13½	2.56
1¾×7½	1.54	1¾×15½	1.65
2¾×7½	2.42	2¾×15½	2.58
1¾×9½	1.58	1¾×17½	1.65
2¾×9½	2.48	2¾×17½	2.60

Example 4. What is the safe load for a 2¾ by 13½-in spruce beam, 18 span?

Solution. From Table VIII, page 639, the safe load for a 1 by 14-in be is 847 lb. Multiplying this by 2.56 the product is 2 168 lb, the safe distribut load for a beam 2¾ by 13½ in in cross-section. For a full, "nominal" si 3 by 14-in, the safe load would be 2 541 lb.

7. Deflection of Steel Beams

General Formula. The DEFLECTION of any steel beam may be found means of Formula (1), page 663.

Example 5. It is required to determine the deflection of a 12-in 31.8 beam, 20 ft in span, under its maximum uniformly distributed load 9.59 tons.

Solution. The load in pounds = 9.59 tons × 2 000 = 19 180 lb; the span inches = 20 ft × 12 = 240 in; c, for a beam supported at both ends and u formly loaded, from the values given under Formula (1), is 0.013; E, for stee 29 000 000 lb per sq in (Table I, page 664); and the moment of inertia, fr the properties of steel I beams, page 355, is 215.8. Substituting these val in Formula (1), page 663,

$$\text{Deflection in inches} = \frac{19\,180 \times 240^3 \times 0.013}{29\,000\,000 \times 215.8} = 0.551 \text{ in}$$

The allowable deflection is $\frac{1}{30}$ of an inch per foot of span, or $\frac{20}{30} = 0.666$ in.

Coefficients of Deflection. In order to save the time required to use t DEFLECTION-FORMULA, COEFFICIENTS OF DEFLECTION have been worked out f different spans and are given in Table III.

Table III. Coefficients of Deflection for Uniformly Distributed Loads*

Span in feet	Fiber-stress, pounds per square inch			Span in feet	Fiber-stress, pounds per square inch

To find the deflection in inches of a section SYMMETRICAL ABOUT THE NEUTRAL AXIS, such as the section of an I beam, channel, zee, etc., divide the coefficient in the table corresponding to the given span and fiber-stress by the depth of the section in inches. To find the deflection in inches of a section NOT SYMMETRICAL ABOUT THE NEUTRAL AXIS, such as the section of an angle, tee, etc., divide the coefficient corresponding to the given span and fiber-stress by twice the distance of the extreme fiber from the neutral axis, obtained from the tables of Chapter X. To find the deflection in inches of a section FOR ANY OTHER FIBER-STRESS than the fiber-stresses given, multiply this fiber-stress by any of the coefficients in Table III, for the given span, and divide by the fiber-stress corresponding to the coefficient used.

Example 6. Required the deflection of a 10-in 25-lb beam of 10-ft span, under its maximum distributed load of 13 tons, the fiber-stress being taken at 16 000 lb per sq in. Table III gives 1.655 as the deflection-coefficient, and dividing this by 10, the depth of the beam in inches, the result is $1.655/10 = 0.1655$, for the deflection at the middle. By Formula (1), page 663, the deflection for the same beam, span, and load $= \dfrac{26\,000 \times 1\,728\,000 \times 0.013}{29\,000\,000 \times 122.1} = 0.1649$ in, the

two results being nearly identical. For the same beam, a span of 18 ft and load of 7.2 tons, the deflection by the table is 0.5363 in; and by Formula (1 0.5328 in, practically the same result.

Safe Loads and Deflection. In the tables of Chapter XV, giving the sa loads for I beams, channels and rolled beams of other cross-sections, the loa given are for the SAFE LIMIT OF DEFLECTION; and the safe loads, also, are giv which will cause deflections of more than 1/360 of the span-length in inches.

Lateral Deflection of Beams. When the unbraced length exceeds t times the width, the tabular safe loads should be reduced in accordance wi the ratios given in the following table in order to insure that the stresses in t compression-flanges should not exceed the allowed safe unit stress:

Length of span	Allowable safe load	Length of span	Allowable safe loa
5 × flange-width	Full tabular load	25 × flange-width	71.9% tabular loa
10 × flange-width	Full tabular load	30 × flange-width	62.5% tabular loa
15 × flange-width	90.6% tabular load	35 × flange-width	53.1% tabular loa
20 × flange-width	81.2% tabular load	40 × flange-width	43.8% tabular loa

"In addition to this lateral deflection which is induced within the beam the action of pure bending-stresses, lateral deflection may be induced by t thrust of floor-arches or other loading acting on an axis perpendicular to t line of principal bending-stress. The thrust of these arches should either neutralized by tie-rods, or the safe carrying capacity of the beam should computed in accordance with the general formulas of flexure to provide the combined stresses due to the action of both vertical and horizontal forc that is to say, the safe loads should be figured around both the axes 1-1 a 2-2, and the unit stress computed so as not to exceed 16 000 lb per sq in."

8. Graphical Determination of Deflection of Beams

The Deflection of a Beam with parallel flanges and constant moment inertia may be DETERMINED GRAPHICALLY. The deflected form is identi with the bending-moment curve for t beam with a load distributed in a fo similar to that of the bending-mome diagram. Fig. 1 is a beam of length L. The moment-curve due to loadi ABC is the deflection-curve due concentrated load P. The deflecti curve is obtained graphically by div ing area ABC into thin vertical str and constructing force and equilibriu polygons (page 296). If a pole-distan be chosen bearing a convenient ra to EI (E is the Modulus of Elastic of the material and I the Moment Inertia of the cross-section of the bea the deflection at any point of the be will have the same ratio to the sca ordinate at that point of the equilibrium-polygon.

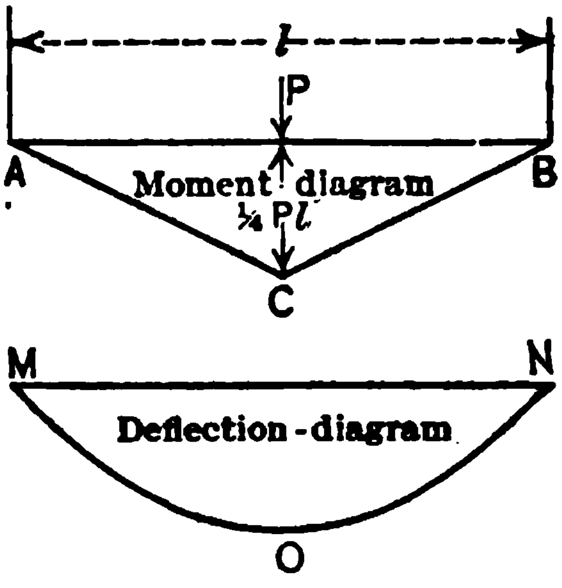

Fig. 1. Moment and Deflection-diagrams of Beam Loaded at the Middle

CHAPTER XIX

STRENGTH AND STIFFNESS OF CONTINUOUS GIRDERS

BY

CHARLES P. WARREN

LATE ASSISTANT PROFESSOR OF ARCHITECTURE, COLUMBIA UNIVERSITY

1. General Considerations

ontinuous Versus Single-Span Girders. A CONTINUOUS GIRDER is one ing upon three or more supports, as distinguished from a SIMPLE GIRDER ich rests upon two supports. Continuous girders, except in reinforced-con- te construction, and in some types of grillage-foundations, are of rare occurre in building-construction. While in almost every building of importance necessary to employ girders resting upon piers or columns, placed from 15 20 ft apart, and while in many cases steel girders could conveniently be obed which would span two and even three of the bays between the supports, y are practically limited to one-story buildings, because in tall buildings it is ter construction to have the vertical rather than the horizontal supports tinuous. Many different opinions are held as to the RELATIVE STRENGTH STIFFNESS of continuous and non-continuous girders, and different formulas e been proposed from time to time; but in this chapter the mathematical ussions will not be given.*

Continuous Girders and Overhanging Girders. In all CONTINUOUS DERS, the end-spans (Fig. 2) are somewhat in the condition of a SIMPLE DER with ONE OVERHANGING END, while the other spans are somewhat in condition of a SIMPLE GIRDER with TWO OVERHANGING ENDS. At each interate support there is a NEGATIVE BENDING MOMENT, the effect of which reduce the bending moments between the supports.

2. Supporting Forces or Reactions of Continuous Girders

ntinuous Girder of Two Equal Spans. Concentrated Load at the dle of Each Span. If a girder of two spans, each equal to l (Fig. 1), be ed at the middle of the left span with P lb, and at the middle of the right with P_1 lb, the reaction at the support R_1 is determined by the formula

$$R_1 = \frac{13\,P - 3\,P_1}{32} \qquad (1)$$

reaction at the support R_2 by

$$R_2 = {}^{11}\!/_{16}\,(P + P_1) \qquad (2)$$

the reaction at the support R_3 by the formula

$$R_3 = \frac{13\,P_1 - 3\,P}{32} \qquad (3)$$

* For the derivation of the following formulas, see an article by F. E. Kidder on this ect, in Van Nostrand's Engineering Magazine, July, 1881.

If $P = P_1$, then each of the end-supports must support $\frac{5}{16} P$ and the mi… support $\frac{22}{16} P$. If the girder is cut so as to make two girders of one … each, then the end-supports will carry $\frac{1}{2} P$ or $\frac{8}{16} P$, and the middle sup… $\frac{16}{16} P$. Hence, it is seen that by … the continuous girder of three spans … reactions of the end-supports are di… ished, while the reaction at the mi… support is increased.

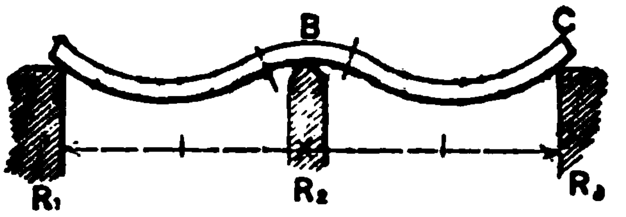

Fig. 1. Continuous Girder of Two Spans

Continuous Girder of Two Sp… Uniformly Distributed Load Over … Span (Fig. 1). Load over each span equals w lb per unit of length. … be the length of the left span and l_1 the length of the right span. Reactio… left support

$$R_1 = \frac{w}{2}\left[l - \frac{l_1^3 + l^3}{4l\,(l + l_1)}\right]$$

Reaction of middle support,

$$R_2 = w\,(l + l_1) - R_1 - R_3$$

Reaction of right support

$$R_3 = \frac{w}{2}\left[l_1 - \frac{l_1^3 + l^3}{4l_1\,(l + l_1)}\right]$$

When both spans are equal to l, the reaction of each end-support is $\frac{3}{8}\,wl$, … of the middle support $\frac{5}{4}\,wl$; hence the girder, by being continuous, reduce… reactions of the end-supports, and increases that of the middle support … 25%.

Continuous Girder of Three Equal Spans. Concentrated Load of P Poun… the Middle of Each Span (Fig. 2).

Reaction of either abutment

$$R_1 = R_4 = \tfrac{7}{20}\,P$$

Reaction of either middle support

$$R_2 = R_3 = \tfrac{23}{20}\,P$$

or the reactions of the two end-supports are $\frac{3}{20}$ less, and those of… two middle supports $\frac{3}{20}$ greater than they would have been had three separate girders of the same cross-section been used, instead of one continuous girder.

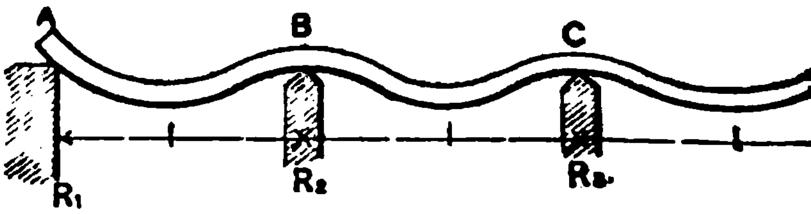

Fig. 2. Continuous Girder of Three Spans

Continuous Girder of Three Equal Spans. Uniformly Distributed Load… Each Span (Fig. 2). The load per unit of length is w lb.

Reaction of either end-support

$$R_1 = R_4 = \tfrac{2}{5}\,wl$$

Reaction of either middle support

$$R_2 = R_3 = \tfrac{11}{10}\,wl$$

Hence the reactions of the end-supports are $\frac{1}{5}$ less, and of the middle su… $\frac{1}{10}$ more, than if the girder were not continuous.

3. Bending Moments of Continuous Girders

Strength of Continuous Girders. The STRENGTH of a girder depends upon its aterial and the shape of its cross-section, and also upon the disposition of the ernal loads imposed upon it. The latter give rise to the BENDING MOMENTS, ich are measures of the tendencies of the external forces, such as the loads d the supporting forces, to bend or to break the girder. It is the difference the numerical values of these BENDING MOMENTS which causes the difference the FLEXURAL STRENGTH of continuous and non-continuous girders of the e cross-section.

Continuous Girders of Two Spans. When a beam is at the point of breaking y flexure, the FLEXURE-FORMULA, $M = SI/c$, is frequently used to calculate a MISAL UNIT STRESS developed in the beam; and when the beam has a rec-gular cross-section the formula takes the form (see page 635)

$$\text{Maximum bending moment} = \frac{\text{Modulus of rupture}^* \times \text{breadth} \times \text{square of depth}}{6} \qquad (11)$$

order that the beam may carry its load with perfect safety, the breaking-load st be divided by a proper FACTOR OF SAFETY. Hence, if the MAXIMUM DING MOMENT of a beam can be found under any conditions, the required ensions of the beam can easily be determined from Formula (11). (See le I, page 557, for the safe values of the FIBER-STRESSES.) The greatest ding moment for a continuous girder of two spans is almost always over the dle support, and is a MINUS BENDING MOMENT, if the plus sign is given to maximum bending moments between the supports. It is the NUMERICAL UE only, however, that is considered.

Continuous Girder of Two Spans. Distributed Load over Each Span. The atest bending moment in a continuous girder of two spans, l and l_1 (Fig. 1), ded with a uniformly distributed load of w lb per unit of length is over the ddle support and is

$$\text{Maximum bending moment} = \frac{wl^3 + wl_1^3}{8\,(l + l_1)} \qquad (12)$$

en $l = l_1$, or both spans are equal,

$$\text{Maximum bending moment} = wl^2/8 \qquad (12a)$$

ch is the same as the maximum bending moment of a beam supported at ends and uniformly loaded over its whole length. Hence a continuous r of two spans uniformly loaded is no stronger as far as flexure is concerned if non-continuous.

ontinuous Girder of Two Equal Spans. Concentrated Load at the Middle Each Span. The greatest bending moment in a continuous girder of two l spans, each of length l, loaded with P lb at the middle of one span, and P_1 lb at the middle of the other, is

$$\text{Maximum bending moment} = \tfrac{5}{32}\, l\,(P + P_1) \qquad (13)$$

* The modulus of rupture is equal to the ultimate flexural unit stress developed in a m when the bending moment is great enough to cause failure, and is expressed in nds per square inch. It usually lies between the ultimate unit compressive strength the ultimate unit tensile strength of the material. (See, also, Chapter XV, page) It is to be noted, that the flexure-formula $M = SI/c$ is not really applicable to s of materials for which the stresses are not proportional to the deformation, nor to homogeneous beams, nor to beams under stresses greater than the elastic limit of material.

When $P = P_1$, or the two loads are equal, this becomes

$$\text{Maximum bending moment} = \tfrac{3}{16}\,Pl \qquad (1$$

or ¼ less than its value when the beam is cut at the middle support.*

Continuous Girder of Three Spans. Uniformly Distributed Load Over E Span. The greatest bending moment in a continuous girder of three sp loaded with a uniformly distributed load of w lb per unit of length, the len of each end-span being l_1 and of the middle span l, is at either of the middle s ports, and is determined by the formula

$$\text{Maximum bending moment} = \frac{wl^3 + wl_1^3}{4\,(3\,l + 2\,l_1)}$$

When the three spans are equal, this becomes

$$\text{Maximum bending moment} = wl^2/10 \qquad ($$

or ⅕ less than what it would be were the beam not continuous.

Continuous Girder of Three Equal Spans. Concentrated Load of P Poun the Middle of Each Span. The greatest bending moment in a contin girder of three equal spans, each of a length l, and each loaded at the mi with P pounds, is

$$\text{Maximum bending moment} = \tfrac{3}{20}\,Pl$$

or ⅖ less than that of a non-continuous girder.

4. Deflection of Continuous Girders

Continuous Girder of Two Equal Spans. Uniformly Distributed Load Each Span. The greatest deflection of a continuous girder of two equal s loaded with a uniformly distributed load of w lb per unit of length is

$$\text{Maximum deflection} = 0.005416\,wl^4/EI$$

in which E is the MODULUS OF ELASTICITY and I the MOMENT OF INERTIA c cross-section of the beam. The greatest deflection of a similar beam supp at both ends and uniformly loaded is

$$\text{Maximum deflection} = 0.013020\,wl^4/EI$$

Hence the deflection of the continuous girder is only about ⅖ that of a continuous girder. The greatest deflection of a continuous girder of two is not at the middle of either span, but between the middle point of a spa one of the abutments. The greatest deflection of a continuous girder c equal spans, loaded at the middle of one span with a load of P lb, and a middle of the other with P_1 lb, is, for the span with the load, P

$$\text{Maximum deflection} = \frac{(23\,P - 9\,P_1)\,l^3}{1\,536\,EI}$$

for the span with load P_1

$$\text{Maximum deflection} = \frac{(23\,P_1 - 9\,P)\,l^3}{1\,536\,EI}$$

When both spans have the same load

$$\text{Maximum deflection} = \tfrac{7}{768}\,Pl^3/EI$$

* In this continuous beam the maximum bending moment is the minus bendi ment over the middle support and in each of the two simple beams the maximum ing moment is a plus bending moment and is between two supports.

The greatest deflection of a simple beam supported at both ends and loaded at the middle with P lb is

$$\text{Maximum deflection} = Pl^3/48\,EI$$

so the deflection of the continuous girder is only 7/16 that of a non-continuous one.

Continuous Girder of Three Equal Spans. Uniformly Distributed Load Over Each Span.
The load per unit of length is w lb.

$$\text{Greatest deflection at the middle of middle span} = 0.00052\,wl^4/EI \qquad (18)$$
$$\text{Greatest deflection in the end-spans} = 0.006884\,wl^4/EI \qquad (19)$$

Hence the maximum deflection of the continuous girder is only about ½ that of a non-continuous girder.

Continuous Girder of Three Equal Spans. Concentrated Load P at the Middle of Each Span.

$$\text{Greatest deflection at the middle span} = 1/480\; Pl^3/EI \qquad (20)$$
$$\text{Greatest deflection at the middle of end-spans} = 11/960\; Pl^3/EI \qquad (21)$$

Hence the maximum deflection of the continuous girder is only 11/20 of that of a non-continuous girder.

Notes on Reactions, Strength and Stiffness of Continuous Girders

Supports and Reactions of Continuous and Non-Continuous Girders. From the foregoing, some conclusions can be drawn which will be of use in deciding whether it is best in any case to use a CONTINUOUS or a NON-CONTINUOUS GIRDER. From the formulas given for the reactions of the supporting forces of the different cases of continuous girders it is seen that the end-supports do not bear as much of the load as they do when the girders are non-continuous. The difference is added to the reactions of the other supports. This might be an advantage in a building in which the girders run across the building, and have their outside ends supported by the side walls and their inside ends by piers or columns. In this case, by using continuous girders, part of the load could be taken from the walls and transferred to the piers or columns. But in cases of this kind, the vibration may have to be considered. If the building is a mill or factory in which the girders support machines, any vibration in the middle span of the girder is carried to the side walls if the girder is continuous; while if non-continuous girders are used, with their ends an inch or so apart, little or no vibration is carried to the side walls from the middle span. In all cases of important construction the supporting forces should be carefully considered.

Relative Strength of Continuous and Non-Continuous Girders. As the RELATIVE STRENGTH of continuous and non-continuous girders of the same cross-section, material and spans, and loaded in the same way, is proportional to their maximum BENDING MOMENTS, the strength of a continuous girder can be calculated, from the formula for its MAXIMUM BENDING MOMENT. From the formulas given for these bending moments for the various cases considered, it is seen that the parts of the girder most stressed are those which come over the middle supports. It is seen, also, that, except in the single case of a girder of two spans uniformly loaded, the strength of a continuous girder is greater than that of a non-continuous girder. But the gain in strength in some instances is not very great, although it is generally enough to pay for making the girder continuous.

Relative Stiffness of Continuous and Non-Continuous Girders. The STI NESS of a girder varies inversely as its DEFLECTION; that is, the less the def tion under a given load the stiffer the girder. From the values given for MAXIMUM DEFLECTION of continuous girders, it is evident that the STIFFNESS a girder is increased by making it continuous; and this is usually the princi advantage in the use of continuous girders. It sometimes happens in buildi construction that it is necessary to use beams and girders of much grea strength than is required to carry the superimposed load, because the deflecti of smaller beams or girders would be too great. But if continuous gir are used they may be made of just the size required for strength, because t deflections are less. Where great stiffness is required, therefore, continu beams or girders should be used if possible, as in the case of grillage-gird (See Example 3, page 679.)

6. Formulas for the Strength and Stiffness of Continuous Girde

Girders of Rectangular Cross-Section. For convenience, the proper form for calculating the strength and stiffness of continuous girders of rectang cross-section are given. The formulas for strength are deduced from the flex formula $M = SI/c$, modified for the rectangular section of breadth b and dept

$$\text{Bending moment} = \frac{b \times d^2 \times S}{6}$$

in which S is the safe unit fiber-stress. This is eighteen times the coeffic A * of Table II, page 628.

STRENGTH. **Continuous Girder of Two Equal Spans. Uniformly Distrib Load Over Each Span.**

$$\text{Breaking-load} \dagger = \frac{2 \times b \times d^2 \times A^*}{l}$$

where b denotes the breadth and d the depth of the girder in inches, and l length of one span, in feet. The values of the constant A are three times values given in Table II, page 628. For long-leaf yellow pine, 201; for Dou fir, 168; chestnut, 132; and for spruce and white pine, 117 lb per sq in, are ommended for the values of A in these formulas.

Continuous Girder of Two Equal Spans. Concentrated Load at the Midd Each Span.

$$\text{Breaking-load} = \tfrac{4}{3} \times \frac{b \times d^2 \times A}{l}$$

Continuous Girder of Three Equal Spans. Uniformly Distributed Load Each Span.

$$\text{Breaking-load} = \tfrac{5}{4} \times \frac{b \times d^2 \times A}{l}$$

Continuous Girder of Three Equal Spans. Concentrated Load at the Mi of Each Span.

$$\text{Breaking-load} = \tfrac{5}{3} \times \frac{b \times d^2 \times A}{l}$$

* See, also, Table I, page 557, and Table XVI, page 647, for safe fiber-stresses.
† Breaking-load in pounds in all cases.

FFNESS. Continuous Girder of Two Equal Spans. Uniformly Distributed d Over Each Span.

e following formulas give the loads which the beams will support without cting more than one-thirtieth of an inch per foot of span.

$$\text{Load on one span} = \frac{b \times d^3 \times e_1}{0.26 \times l^2} \tag{27}$$

ntinuous Girder of Two Equal Spans. Concentrated Load at the Middle of h Span.

$$\text{Load on one span} = {}^{16}\!/_{9} \times \frac{b \times d^3 \times e_1}{l^2} \tag{28}$$

Continuous Girder of Three Equal Spans. Uniformly Distributed Load Over h Span.

$$\text{Load on one span} = \frac{b \times d^3 \times e_1}{0.33 \times l^2} \tag{29}$$

ntinuous Girder of Three Equal Spans. Concentrated Load at the Middle ch Span.

$$\text{Load on one span} = {}^{20}\!/_{11} \times \frac{b \times d^3 \times e_1}{l^2} \tag{30}$$

he value of the constant e_1 is obtained by dividing the MODULUS OF ELAS- TY by 12 960; and, for the three woods most commonly used as beams, the wing values may be taken:

ong-leaf yellow pine, 116; white pine, 77; spruce, 92; Douglas fir, 116. other woods, see Table I, page 664.)

r Continuous Steel Beams the requisite size may be found by first com- ing the MAXIMUM BENDING MOMENT, by means of Formulas (12) to (15), then selecting a beam that has a

$$\text{SECTION-MODULUS} = \frac{3 \times \text{maximum bending moment in ft-lb}}{4\,000} \tag{31}$$

lues for the SECTION-MODULI for the different shapes of rolled steel used as s are given in the tables in Chapter X.

mple 1. What steel beam should be used to support two loads of 16 000 ch, concentrated at the middle of two spans of 10 ft each, the beam being nuous?

tion. Formula (13*a*) gives the maximum bending moment as $\frac{3}{16}$ *Pl*, or 0 ft-lb. Therefore, from Equation (31), a beam having a section-modulus l to 3 × 30 000/4 000 or 22.5 should be used. From the Table IV, page it is found that a 9-in 30-lb beam has a section-modulus of 22.5, and a 25.4-lb beam a section-modulus of 24.4. Either of these beams will there- answer, the 10-in beam being the cheaper, however, and also the stiffer.

mple 2. A steel beam continuous over three spans is required to support ormly distributed load of 1 000 lb per lin ft. The two end-spans are 12 ft , and the middle span 10 ft. What should be the size and the weight of the n used?

tion. The maximum bending moment is found by Formula (14), and is

$$\frac{1\,000 \times 1\,000 + 1\,000 \times 1\,728}{4\,(30 + 24)} = 12\,630$$

The section-modulus, by Equation (31), must equal $3 \times 12\,630/4\,000 =$ which requires a 7-in 15.3-lb beam (Table IV, page 355).

If the beam were not continuous an 8-in 18.4-lb beam would be require the 12-ft spans, and a 7-in 15.3-lb beam for the 10-ft span.

For a beam of two equal spans, loaded uniformly, the strength is the san though it were not continuous.

The formulas given for the reactions at the supports, and for the deflec of continuous girders with concentrated loads, were verified by Mr. Kidd means of careful experiments on small steel bars. The remaining forr were verified by comparing them with the formulas of other authorities it was possible to do so. In regard to some of the cases given the autho never seen any discussion of them in any work on the subject.

7. Continuous Girders in Grillage-Foundations

Grillage-Beams Considered as Inverted Continuous Girders. As stat the beginning of this chapter, CONTINUOUS GIRDERS, as such, are seldom us building-construction, although their employment in grillage-beam footings i

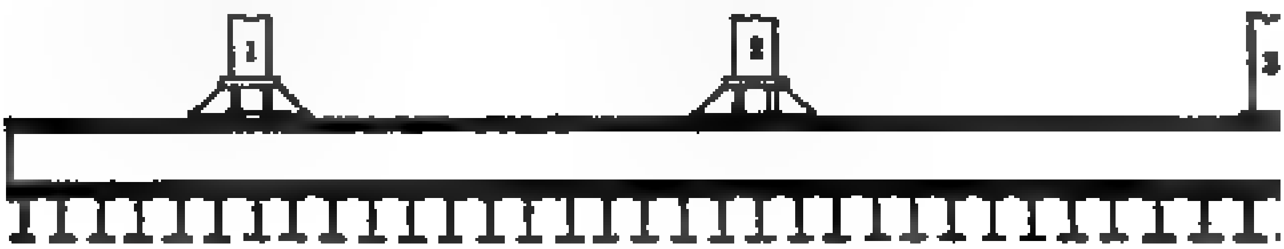

Fig. 3. Continuous Girder in Grillage-foundation

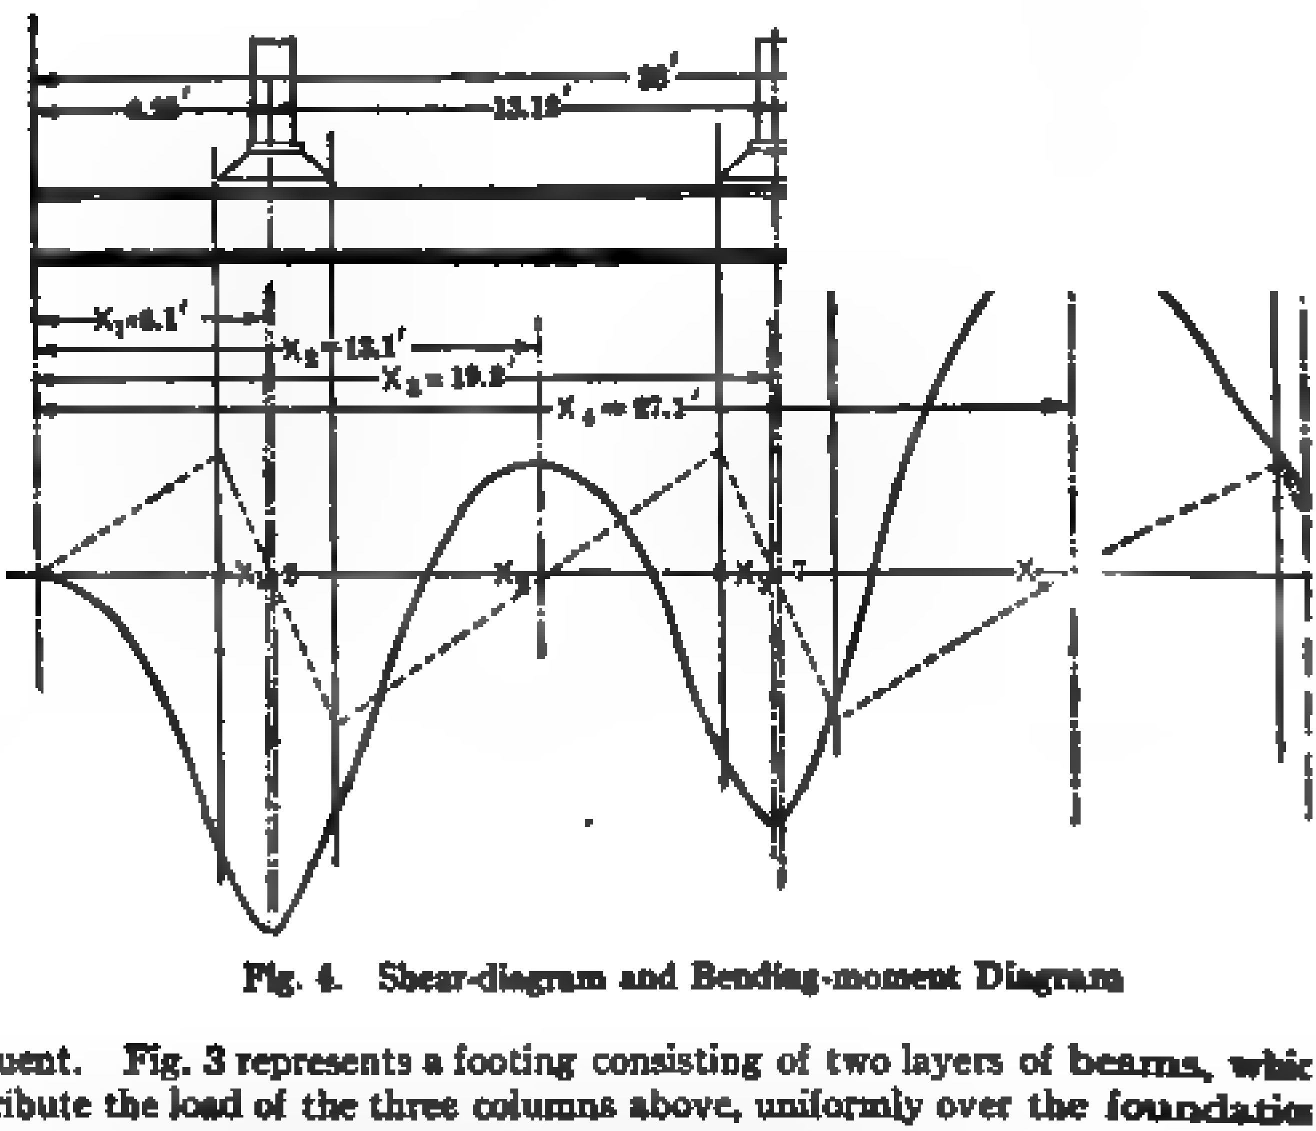

Fig. 4. Shear-diagram and Bending-moment Diagram

quent. Fig. 3 represents a footing consisting of two layers of beams, whic tribute the load of the three columns above, uniformly over the foundatio By inverting the footing the three columns become the supports or reaction the upper layer of beams, a continuous girder, loaded with a uniformly di uted load which is the pressure of the lower layer. As in practice the co

loads are never equal, and the distance between the columns seldom equal, it is necessary to project the continuous girder beyond the most heavily loaded column in order to insure a uniform pressure upon the lower layer. Because of these limitations none of the formulas previously deduced can be applied, although the principles upon which they are based hold good.

Maximum Bending Moment. Since the REACTIONS in this case are the given column-loads it is required first to find the MAXIMUM BENDING MOMENT. From what has already been said about continuous girders, it is evident that the point of maximum bending moment may be under columns 1 or 2, or between the columns. Since the maximum bending moments are the POINTS OF NO SHEAR, construct the SHEAR-DIAGRAM, find where the shear passes through zero, and calculate the bending moments at these points. The maximum bending moment is determined, as in examples 1 and 2, in order to determine the SECTION-MODULUS of the girder.

Example 3. The continuous girder under columns 1, 2 and 3 (Fig. 3) is 33 ft long; the overhang, to the left of column 1, 6.25 ft; the distance between columns 1 and 2, 13.12 ft; between columns 2 and 3, 12.88 ft; and from column 3 to the right edge of the girder, .75 ft. The column-loads are as follows: on column 1, 565 tons; on column 2, 600 tons; and on column 3, 255 tons.

The column-loads may be considered uniformly distributed over parts of the girder by the bases, which are 3 ft wide under columns 1 and 2 and 18 in wide under column 3. The UNIT PRESSURE under column 1, therefore, is $565/3 = 188.3$ tons; under column 2, $600/3 = 200$ tons; and under column 3, $255/1.5 = 170$ tons. The unit pressure under the continuous girder is

$$(565 + 600 + 255)/33 = 43 \text{ tons}$$

The first step in the calculation of the girder is the determination of the POINTS OF NO SHEAR and the plotting of the SHEAR-DIAGRAM in Fig. 4. It is obvious from the shear-diagram that there are four points of no shear and consequently four points of POSSIBLE MAXIMUM BENDING MOMENT. The first of these is under column 1, the second between columns 1 and 2, the third under column 3 and the fourth between columns 2 and 3. The bending-moment diagram is shown by the solid curved line in Fig. 4. The points of contraflexure or no bending moment are the intersections of this line with the horizontal line of reference.

The SHEAR-DIAGRAM,* shown by the broken line in Fig. 4, may be constructed as follows:

$$V_1\dagger = +43 \text{ tons per ft} \times (6.25 - 1.5 = 4.75 \text{ ft}) = +204.25 \text{ tons}$$

$$V_2 = (+43 \text{ tons per ft} \times 6.25 \text{ ft}) - 565/2 \text{ tons} = +268.75 - 282.5 = -13.75 \text{ tons}$$

This shows that x_1, the point of no shear, lies between points 1 and 2. To find this point let y be its distance beyond or to the right of point 1. Then, the EQUATION FOR NO SHEAR is 43 tons $\times$ (4.75 ft + y ft) = $188.3 \times y$, or $204.25 + 43\,y = 188.3\,y$, from which $145.3\,y = 204.25$ and $y = 1.4$ ft: hence x_1, the FIRST POINT OF NO SHEAR, is 4.75 ft + 1.4 ft, or 6.1 ft from the left end.‡

The SECOND POINT OF NO SHEAR, x_2, is such a distance from the left end that the DOWNWARD SHEARING-FORCE of 565 tons from column 1 is neutralized by

* The upward forces are here called plus or positive and the downward forces minus or negative.

† V_1 is taken at point 1, the left edge of base of Column 1, V_2 at point 2, at the axis of column 2, etc.

‡ The following computations are carried out to one decimal-place, only, the nearest approximate values being used.

an equal UPWARD SHEARING-FORCE of 43 tons per ft. on x_3 ft. Hence $x_2 = 565/$
$= 13.1$ ft.

$V_6 = +43$ tons per ft $\times$ [(6.25 + 13.12 − 1.5) = 17 9 ft] − 565 tons
$= 769.7 - 565 = +204.7$ tons

$V_7 = +43$ tons per ft $\times$ (6.25 + 13.12 = 19.4 ft) − (565 + 600/2 tons)
$= +834.2 - 865$ tons $= -30.8$ tons

This shows that the THIRD POINT OF NO SHEAR, x_3, lies between 6 and 7. L
y be its distance to the right of point 6. The equation for no shear at th
point is 43 tons $\times$ (17.9 ft + y ft) = 565 tons + (200 tons $\times$ y ft), or 769.7 + 43
= 565 + 200 y. from which 157 y = 204.7 and y = 1.3 ft. Hence x_3, the THI
POINT OF NO SHEAR, is 17.9 ft + 1.3 ft = 19.2 ft from the left end.

The FOURTH POINT OF NO SHEAR, x_4, is such distance from the left end th
the DOWNWARD SHEARING-FORCE of columns 1 and 2, amounting to 565 + 6
or 1165 tons, is neutralized by an equal UPWARD SHEARING-FORCE of 43 to
per ft on x_4 ft. Hence $x_4 = 1\,165/43 = 27.1$ ft.

Having found the points of no shear, the BENDING MOMENT at these poin
may now be determined.

M at $x_1 = 43$ tons $\times$ 6.1 ft $\times$ 6.1/2 ft − 188.3 tons $\times$ 1.4 ft $\times$ 1.4/2 ft
$= +615.5$ ft-tons

M at $x_2 = 43$ tons $\times$ 13.1 ft $\times$ 13.1/2 ft − 565 tons $\times$ 6.8 ft $= -152.4$ ft-to

M at $x_3 = 43$ tons $\times$ 19.2 ft $\times$ 19.2/2 ft − 565 tons $\times$ 12.9 ft − 200 T $\times$ 1.3
$\times$ 1.3/2 = +467 ft-tons

M at $x_4 = 43$ tons $\times$ 27.1 ft $\times$ 27.1/2 ft − 565 tons $\times$ 20.8 ft − 600 tons
$\times$ 7.7 ft $= -582.2$ ft-tons

The MAXIMUM BENDING MOMENT therefore is at x_1 and equals 615.5 ft-tons*
1 231 000 ft-lb. Substituting in Formula (31), the SECTION-MODULUS is foun
to be $\frac{3 \times 1\,231\,000}{4\,000} = 923.2$. The following beams could be used, as far
flexure is concerned. For investigations of the resistance of the girders to we
buckling or crippling, see Chapter II, pages 182 to 184, and Chapter X
pages 567 to 569.

Four standard 24-in 110-lb I beams, section-modulus of each, 239.1 (page 35

Three Bethlehem 30-in 120-lb I beams, section-modulus of each, 349.3 (pa
357)

Three Bethlehem 24-in 140-lb girder-beams, section-modulus of each, 350
(page 358)

Two Bethlehem 28-in 180-lb girder-beams, section-modulus of each, 518
(page 358)

The 28-in and 30-in beams are stiffer than the 24-in beams, have a small
total amount of steel and cost less than the others for the number of bea
required.

* The bending moments at x_1 and x_4 have very nearly the same numerical values, a
in the computations the retaining or dropping of figures in the second decimal-place m
change the result and make the value at x_4 slightly greater than at x_1.

CHAPTER XX

RIVETED STEEL PLATE AND BOX GIRDERS

By

CHARLES P. WARREN

LATE ASSISTANT PROFESSOR OF ARCHITECTURE, COLUMBIA UNIVERSITY

1. General Notes on Plate and Box Girders

Types of Riveted Girders. Girders built up of plates and angles, as shown in section in Figs. 1 to 4, are extensively used. This is undoubtedly owing to the simplicity of their construction, to the comparatively low cost of the shapes of which they are fabricated and to their adaptability to any arrangement of loads or to any span for which girders are usually required. Riveted girders, however, are seldom made for spans greater than 60 ft and are seldom more than 6 ft in depth. The most common forms of these girders are shown in Figs. 2 and 4.

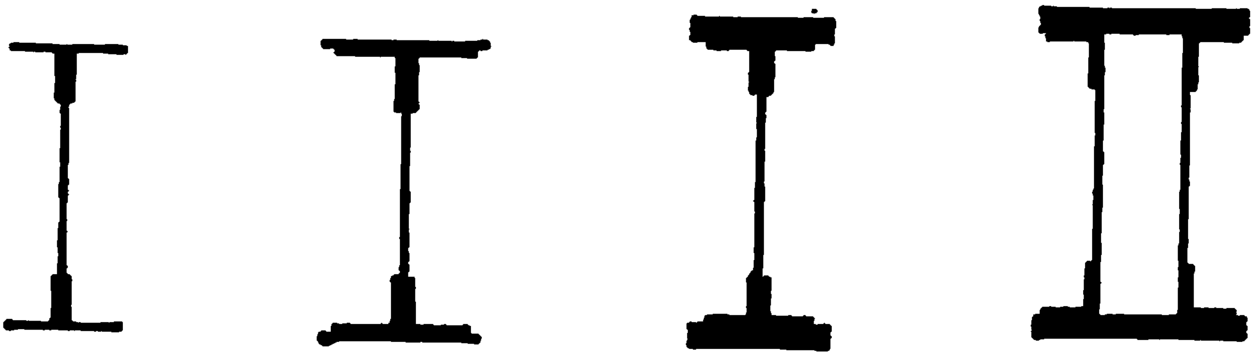

Fig. 1 Fig. 2 Fig. 3 Fig. 4

Types of Riveted Girders

The girders with a single vertical plate called the WEB are usually called PLATE GIRDERS, and those with double or triple webs, BOX GIRDERS. Plate girders are more economical than box girders, and more accessible for painting and inspection; but box girders are stiffer laterally and should always be used where great length of span requires wide flanges. In general, it may be said that plate girders should be used to support floor-beams and floor-arches and walls not over 12 in thick, and that box girders should be used where a flange-width greater than 12 in is required. The girder shown in section in Fig. 1 has no flange-plates and should be used only for comparatively light loads and short spans, and never to support masonry.

Flange and Web. The term FLANGE, as applied to riveted girders, includes all the metal in the top or bottom parts of the girder, exclusive of the web-plates.* The DEPTH of a riveted girder is the distance between the centers of gravity of the flanges; but in practice this is usually taken as the DEPTH OF THE WEB-PLATE, and the word will be so used in this chapter. The top and bottom of the flange-angles extend ¼ in beyond the top and bottom of the web-plate. (See the figure in Table IV, page 706.) STIFFENERS are short pieces of angles

* This may be modified, however, as some engineers include one-sixth of the web-area in the effective flange-area. See, also, Flange-Area in the examples of this chapter.

riveted to the web at intervals, to keep it from BUCKLING. They should f closely against the horizontal legs of the flange-angles, and should alwa be used at the supports and under concentrated loads.

Economic Depths of Girders. The depth of a riveted girder may va from one-tenth to one-fifteenth or, in exceptional cases, one-sixteenth the spa The greatest economy of material is said to be obtained when the depth is on twelfth the span. Thus for a 36-ft span a 3-ft girder should be used if tl conditions will permit; but the least depth should be 1/15 of 36, or about 2 5 in or, in exceptional cases, 1/16 of 36, or 2 ft 3 in. A girder is said to have i ECONOMIC DEPTH when the amount of material in the flanges is equal to th in the web, and there are no cover-plates. The rule holds approximate when there are cover-plates.

The Width of the Top Flange should not be less than one-twentieth tl distance between lateral supports; or if there are no lateral supports, then n less than one-twentieth the span.

Arches Between Girders, or floor-beams riveted to the sides of girders, m be considered as LATERAL SUPPORTS.

2. Details of Construction of Plate and Box Girders*

General Requirements for Plate and Box Girders. The following r quirements are those which must be generally satisfied in the design of rivet girders.

(1) All the connections and details of the several parts shall be of such streng that, upon testing, rupture shall occur in the body of the members rather th in any of their details or connections.

(2) In members subject to tensile stress full allowance shall be made for t reduction of the section by the rivet-holes.

(3) The webs of plate girders, when they cannot be obtained in one lengt must be spliced at all joints by a plate on each side of the web.

(4) Tees must not be used for splices.

(5) Stiffeners shall be used at the ends of all girders, wherever there are co centrated loads, and elsewhere when the shearing-stress is greater than t resistance to buckling.

(6). The PITCH, that is, the distance between centers of rivets, shall not e ceed 6 in, nor 16 times the thickness of the thinnest outside plate, and it sh not be less than 2¼ in for ¾-in rivets, or 2⅝ in for ⅞-in rivets, in a straig line.

(7) The rivets used should be ¾ in in diameter for plates from ⅜ to ⅝ thick, and ⅞ in in diameter for plates of greater thickness.

(8) The distance between the edge of any piece and the center of a riv hole must never be less than 1¼ in.

(9) In PUNCHING plates or other members, the diameter of the die shall in case exceed the diameter of the punch by more than 1/16 in.

(10) All RIVET-HOLES must be so accurately punched that when the seve parts forming one member are assembled, a rivet, 1/16 in less in diameter th the hole, can be inserted, hot, into any hole without REAMING or stressing t metal by the use of drift-pins.

(11) The rivets when driven must completely fill the holes.

(12) The RIVET-HEADS must be hemispherical, except where flush surfa are required, and of uniform size throughout for rivets of the same size. Th must be full and neatly made, and be concentric with the rivet-holes.

* These requirements are taken largely from Birkmire's "Compound Riveted Girder

(13) Whenever possible, all rivets must be MACHINE-DRIVEN.
(14) The several pieces forming one built member must fit closely together, d, when riveted, must be free from twists, bends or open joints.
(15) Girders 60 ft and less in length seldom require SPLICING, as the plates and gles can readily be obtained in such lengths. In splicing the top flange, n of two or more thicknesses, no additional COVER-PLATE will be required r the joint, but the ends should be planed true and butt closely. The rivets uld be spaced closer near the joint.
(16) The plate covering the bottom flange must be of the same area as the tes joined, and of sufficient length to take a number of rivets equal to the ngth of the cover-plate.

3. Design of Plate and Box Girders

The Principal Steps in the Design of Riveted Girders. In designing iveted girder to sustain safely a given load, the following steps are necessary:
(1) The determination of the required flange-area.
(2) The determination of the thickness of the web to resist
 (a) Shearing.
 (b) Buckling. This step also determines if stiffeners are necessary.
(3) The determination of the number and pitch of the rivets.
(4) The approximate weight of the girder.
(5) The determination of the length of the flange-plates when more than one equired for each flange.

(1) **The Flange-Area.** In determining the FLANGE-AREA of riveted girders, is customary to assume that the bending moments are entirely resisted by the er and lower flanges, the web being assumed to resist the shear only. Just t should be included in the flange-area is a question on which engineers differ. e include the flange-plates and angles and one-sixth of the web-area, others flange-plates and angles only, while others include the flange-plates and only horizontal legs of the angles, the vertical legs being considered as belonging the web. In compression-flanges, usually the upper ones, the gross section- may be taken, provided the rivets are machine-driven and fill completely holes; but in tension-flanges, usually the lower ones, the net area is taken, t is, the gross area minus the area of the greatest number of rivet-holes in cross-section, since the stresses of tension are not transmitted through the s as are those of compression.
A general FORMULA* FOR DETERMINING THE FLANGE-AREA, which applies to conditions of loading is

$$\frac{\text{Area of one flange}}{\text{in square inches}} = \frac{\text{maximum bending moment in foot-tons}}{\text{depth of web in feet} \times \text{safe unit fiber-stress in tons}}$$

$$A = M_{max}/dS \qquad (1)$$

* This may be derived from what is sometimes called the PLATE-GIRDER FORMULA, $M_{max} = SAd$, in which S is the safe unit bending-stress in the flange at the section of mum bending moment, A is the area of the cross-section of either flange and d is ap-ately the depth of the girder. Of course the units must be the same in both mem-of the equation. If the center of moments is taken at the center of gravity of the s-section of either flange-area and if the area of metal resisting bending is considered concentrated in the flanges, the depth of each being very small compared to that e girder-depth, then SA is the total horizontal stress in either flange, d its lever-and SAd the resisting moment of the cross-section, equal to M_{max}. Hence $A = M_{max}/dS$. Another method uses the section-modulus, $I/c = M/S$, in determining the e-areas and proportioning the girder. (See pages 706 to 716.)

Rules for finding the MAXIMUM BENDING MOMENT for different conditions loading are given in Chapter IX.

S, the SAFE UNIT FIBER-STRESS FOR FLANGE-BENDING, was formerly taken from 13 000 to 16 000 lb per sq in, the tables in the manufacturers' handbo giving the safe loads, etc., for riveted girders, varying in regard to this stress.*

If it is required to compute the SAFE UNIFORMLY DISTRIBUTED LOAD fo girder already constructed or designed, the following formula † may be u The safe load in pounds, uniformly distributed is

$$W = \frac{8 \times \text{net area of bottom flange} \times \text{depth in ft} \times S}{\text{span in feet}}$$

or

$$W = 8\,AdS/l$$

From the result the weight of the girder itself should be subtracted.

For the SAFE CONCENTRATED LOAD AT THE MIDDLE OF THE SPAN take one- the result obtained by formula (2) and subtract the weight of girder. Case IV, page 326.)

(2) **The Thickness of the Web.** The thickness of the web is determ by its resistance to VERTICAL SHEARING. Whether or not stiffeners shall be is determined by the resistance of the web to BUCKLING.

(a) **Shearing.** To resist the vertical shear the NET SECTIONAL AREA OF WEB in square inches must be

$$A = \frac{\text{the maximum vertical shear}}{S}$$

or

$$A = V_{max}/S$$

V and S being both in tons, S is taken at 10 000 ‡ lb or 5 tons per sq in. Table II, page 703.)

The MAXIMUM VERTICAL SHEAR in any beam or girder is at the greater rea and is equal to it.

For a girder supported at both ends and uniformly loaded with a loa the MAXIMUM VERTICAL SHEAR is

$$V_{max} = W/2$$

For a girder supported at both ends and loaded at the middle with a lo

$$V_{max} = P/2$$

For a girder supported at both ends and loaded as in Fig. 7,

$$V_{max} = Pm/l = R_1$$

For a girder supported at both ends and loaded with two equal concent loads P, P, equally distant from the middle, as in Fig. 8,

$$V_{max} = P = R_1 = R_2$$

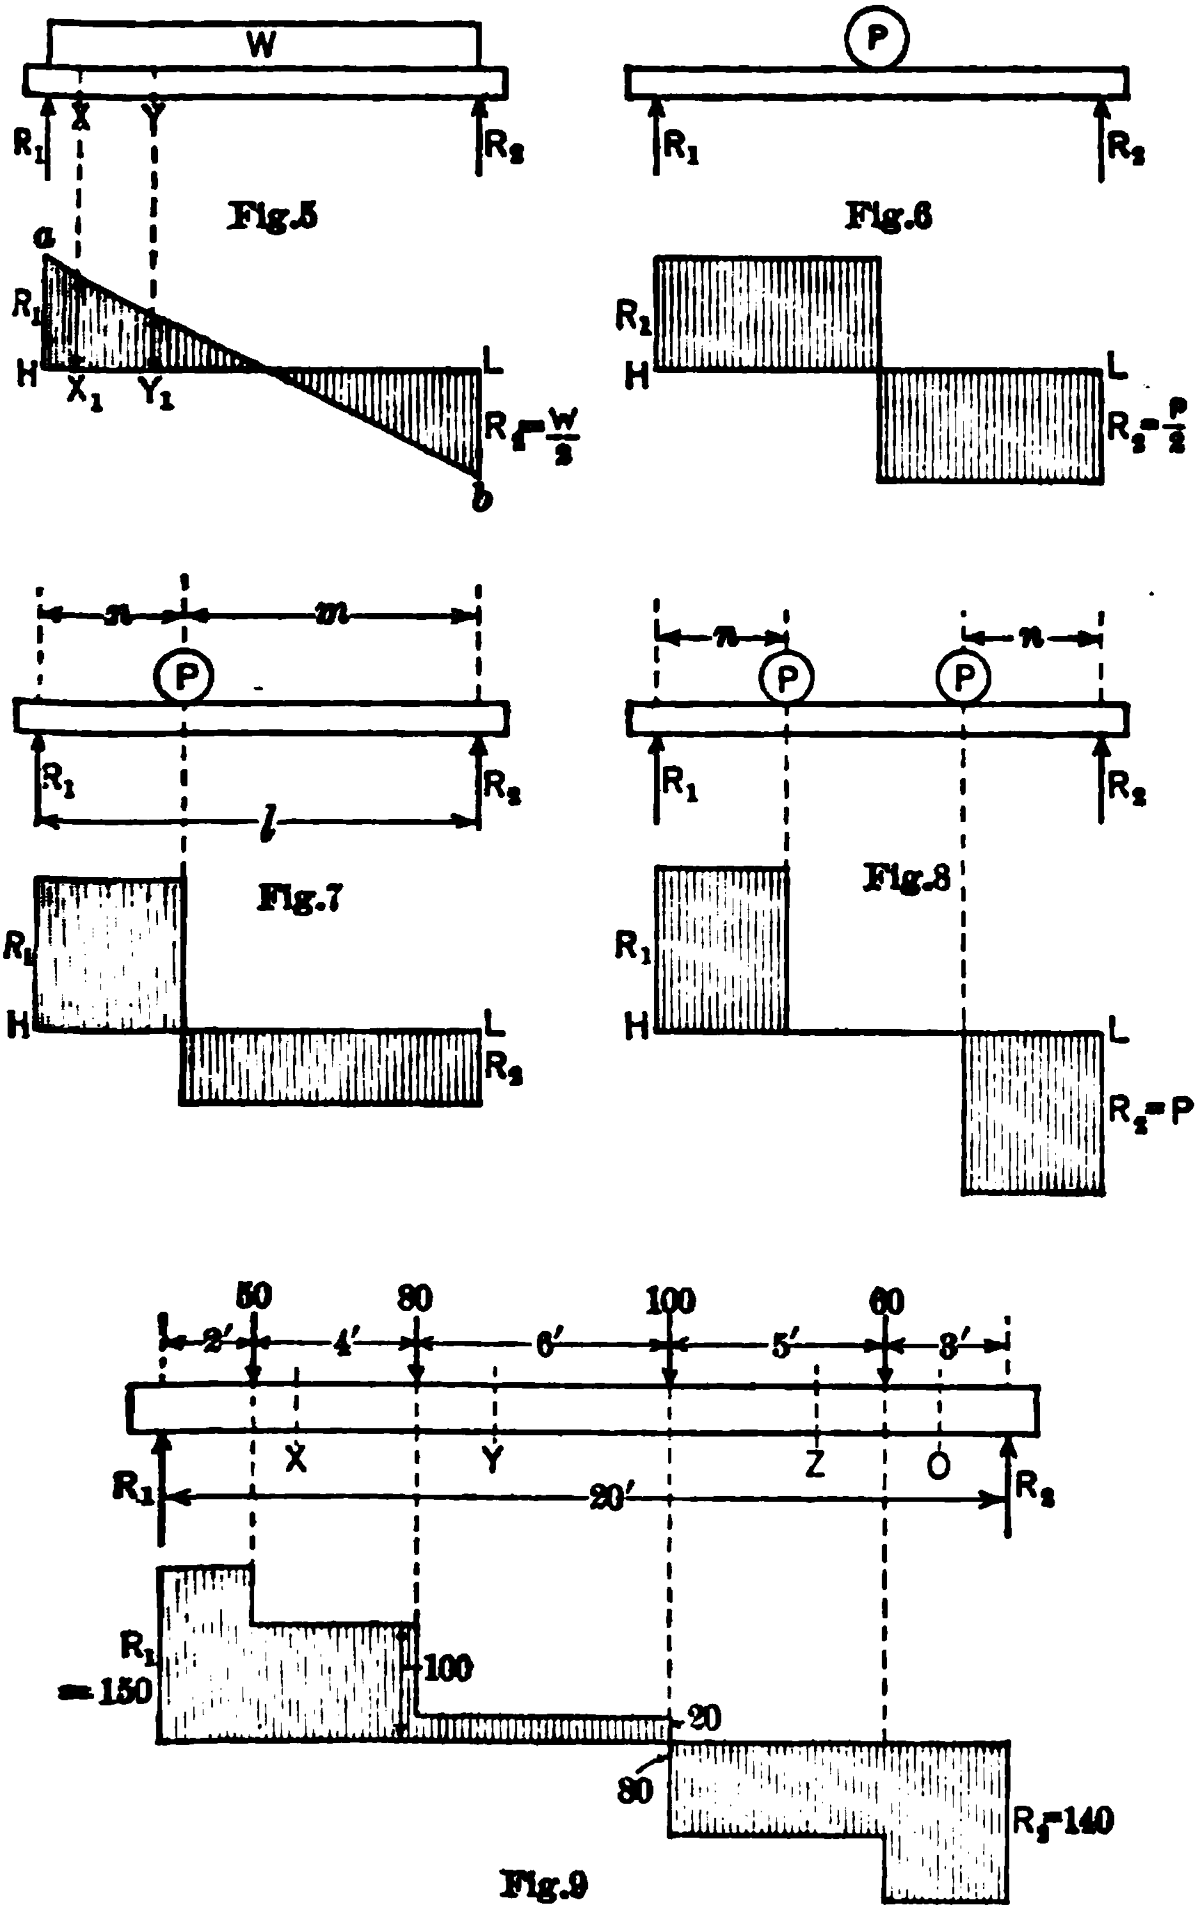
For combinations of loads the maximum vertical shear will equal the g reaction. The method of determining the REACTIONS at the supports of a or girder is given in Chapter IX, Subdivision 1. The VERTICAL SHEA

* See Chapter XV, paragraphs relating to riveted single and double-beam gird foot-note with same, pages 603 and 604; also page 704. The value in most city now 16 000 lb per sq in.

† From Formula (1) just explained, and from Case V, page 326, $M_{max} = SA$ $M_{max} = Wl/8$. Hence $Wl/8 = SAd$ and $W = 8\,AdS/l$.

‡ This is a conservative value. The Carnegie Pocket Companion and the b laws of most cities permit 10 000 lb per sq in for steel.

ICE at any given vertical section of a beam or girder between the supports is e algebraic sum of all the vertical external forces acting on the beam to the



Figs. 5 to 9. Diagrams for Vertical Shears for Different Loadings

f that section, forces acting upwards being considered as plus, and those g downwards being considered as minus.

s, in the case of the beam shown in Fig. 9, the REACTION R_1 will be l, by the method explained in Example 2, page 323, and by Formulas (2)

and (3), page 323, to be 150 lb, and that at R_2 to be 140 lb. The shear at v
ous sections may be found by applying the foregoing definition of VERTI
SHEAR, thus:

Shear at $X = +150 - 50 = +100$ lb
Shear at $Y = +150 - 50 - 80 = +20$ lb
Shear at $Z = +150 - 50 - 80 - 100 = -80$ lb
Shear at $O = +150 - 50 - 80 - 100 - 60 = -140$ lb

The manner in which the VERTICAL SHEAR varies between the supports, u
different dispositions of the loads, is shown graphically by the hatched are
Figs. 5 to 9; in the first three cases W and P are assumed to have the s
value.

When the load is UNIFORMLY DISTRIBUTED the VERTICAL SHEAR can be fo
graphically by laying off vertically R_1 and R_2 to a scale of pounds, and dra
the line ab, Fig. 5. The shear at X will then be represented by the ordi
X_1 and the shear at Y by Y_1, and they can readily be scaled.

(b) Buckling.* The safe resistance of the web to BUCKLING, in pounds
square inch, may be determined by the formula

$$S_b = \frac{10\,000}{1 + \dfrac{d^2}{3\,000\,t^2}}$$

in which S_b is the safe buckling value in pounds per square inch, d is the d
of the web in the clear between flange-plates in inches and t is the thickne
the web in inches. When this resistance is less than the UNIT STRESS
VERTICAL SHEAR at any section, stiffeners must be used.

Stiffeners. These should be made of ANGLES, not less than 3½ by 3½ b
in in size. They should always be tightly fitted between the flange-angle
as to support the horizontal flanges.
order to bring the stiffeners in contact
the web and the vertical leg of the an
FILLERS, of the same thickness as
flange-angles, are generally used, as sh
in Fig. 10. Where there are several gi
exactly alike, something may be save
omitting the fillers and BENDING THE
FENERS, as shown in Fig. 11. This b
ing, however, can be done properly,
by the use of special dies, and costs
than the fillers unless there are m
stiffeners. The SPACING OF STIFFENE
more a matter of judgment and expe
than of exact calculation. SHEAR-DIAG
shown in Figs. 5 to 9, are of great assistance in visualizing shearing-str
The general rule is to place the stiffeners not farther apart than the dep
the full web-plate on girders over 3 ft in depth, with a maximum spacing of
On girders under 3 ft in depth they are placed 3 ft apart. Girders 2 ft an
in depth require no stiffeners. On girders supporting distributed loads the
generally placed nearer together at the ends than towards the middle.

Fig. 10. Stiffeners with Fillers

Fig. 11. Bent Stiffeners

* See Table III, page 705, and also in Chapter XV, the paragraphs and foot
pages 567 to 569, relating to the web-buckling of beams and girders. The fo
used for web-buckling in Table III, page 705, is the formula that was used in the B
Steel Company's Manual, and as the values computed by it vary but little from
deduced by the Cambria formula (see page 568), Table III is retained as it is.

Stiffeners should always be placed at the ends of girders and directly over the edge of each support, as shown in Fig. 18, and wherever there are concentrated loads. On plate girders the stiffeners are always placed on each side of the web; on box girders on the outside only.

The Bearing of Girders. This depends somewhat upon the character of the loading, but a safe general rule is to make the BEARING of the girder beyond the edge of the support equal to ONE-HALF THE DEPTH OF THE GIRDER.

(3) The Number and Pitch of the Rivets. **(a) Rivets in Web-Legs of Angles.** It will readily be seen that when a plate or a box girder is loaded, the tendency of the bending moments is to cause the flange-plates and angles to SLIDE HORIZONTALLY past the web; this tendency is resisted by the rivets which connect the angles with the web. The TOTAL AMOUNT OF THIS TENDENCY TO SLIDE, called the HORIZONTAL FLANGE-STRESS, between any section of the flange and the nearer end of the girder, is equal to the BENDING MOMENT at that point DIVIDED BY THE DEPTH OF THE WEB.* The TOTAL NUMBER OF RIVETS between that section and the nearer end must be such that their combined resistance to SHEARING or BEARING, whichever has the lower value, shall equal this horizontal flange-stress at the section; or

$$\text{number of rivets} = \frac{\text{horizontal flange-stress}}{\text{bearing or shearing of one rivet}} \qquad (5)$$

and the total number of rivets in the web-angle from end to end is twice this, or

$$\text{total number of rivets} = \frac{2 \times \text{maximum bending moment}\dagger \text{ in foot-pounds}}{\text{depth of web in feet} \times \text{least resistance of one rivet}} \qquad (6)$$

If the NUMBER OF RIVETS determined by formula (6) is such that they would be more than 6 in apart, then the number must be increased, as in no case should they have a greater PITCH than 6 in.

(b) Rivets in Flange-Legs of Angles. WITH A SINGLE COVER-PLATE. For girders with a single cover-plate, it is customary to put the same number of rivets in the flange-leg as in the web-leg for a distance of 3 ft from the ends of the girder, STAGGERING the rivets as in Fig. 15. Beyond that point to the middle of the girder one-half the number of rivets will be sufficient, provided this will not give them a greater pitch than 6 in.

WITH TWO OR MORE COVER-PLATES. When two or more cover-plates are used, each plate must have sufficient rivets between the end of the plate and the point where its resistance is required, that is, for example, between a and b, Fig. 13, to transfer to the angle and flange-plates between, an amount EQUAL TO THE SAFE STRENGTH OF THE PLATE. From this point to the middle point of the girder, the rivets can be spaced according to the rule for the greatest pitch.

(c) Rivets in Stiffeners. The spacing of rivets in the stiffeners is generally determined by the rules given for the pitch of rivets. Further explanation of the method of determining the spacing of rivets will be found in the following examples.

(4) The Approximate Weight of the Girder. In determining the size of a riveted girder to support a given load, it is desirable to be able to add to the

* See Formula (1), page 683, and foot-note relating to it. $M = SAd$, and hence $SA = M/d$, SA being the total amount, in pounds, of the tendency to slide, and S being the horizontal unit, flange, fiber-stress in pounds per square in, due to flexure. A is the area in square inches of the cross-section of the flange and d is the approximate depth of the girder.

† Because the maximum horizontal flange-stress is equal to the maximum bending moment divided by the girder-depth, or $S_{max}A = M_{max}/d$.

superimposed load the WEIGHT OF THE GIRDER itself, as this often forms a c
siderable part of the load to be supported. The following empirical rule
often used to determine the approximate weight of a plate or box girder:

$$\text{Weight of girder between supports, in tons} = Wl/700$$

in which W equals the load to be supported, in tons, and l equals the spa
feet. The constant 700 was determined for girders of from 35 to 50 ft long,
may be used without much excess for girders of shorter spans.

(5) The Determination of the Lengths of the Flange-Plates. Fo
methods used to determine these, see the following examples.

4. Explanation of Tables

The Calculations for the Design of Riveted Girders may be gr
facilitated by the use of Tables I, II, III and IV at the end of this chapt

Table I gives the sectional area that should be deducted for rivet-hol
plates of different thicknesses. In computing this table 1/8 in was added t
diameter of the rivet to allow for the injury to the metal caused by pun
and also to allow for the expansion of the heated rivet.

Table II gives the safe shearing value for web-plates for various depths
thicknesses, and the deduction to be made for each 3/4-in or 7/8-in rivet.

Table III gives the safe resistance to buckling per square inch of net sec
and also the total safe resistance in pounds for the more common sizes of
plates, with two rivet-holes deducted. It is very seldom that any vertica
tion between the stiffeners contains more than two rivet-holes. Tables g
the dimensions and properties of angles will be found in Tables XI and
pages 362 to 367, and the shearing value and bearing values of rivets are
in Tables II and III, pages 418 and 419.

Table IV gives the elements of riveted plate girders of various depths,
which it is possible to select economical sections for almost any ordinary c
tion of loading.

5. Examples of Plate and Box Girders

Example 1. It is required to support the floor over a room 50 by 6
means of riveted steel plate girders, placed across the room, 16 ft on
The room above is to be used for general assembly purposes. The flo
are of wood and there is a plaster ceiling on the under side of them. Th
of the girder is required.

First Step. The Load. The first step is to determine the load to be su
by each girder. The floor-area supported by each girder is 50 by 16 ft, o
ft The weight of the floor-construction between the girders will not
25 lb per sq ft, and an allowance of 100 lb per sq ft for the live load
ample. The unit load, 125 lb × 800 = 100 000 lb, or 50 tons, the lo
carried by the girder. To this should be added the weight of the gird
Substituting in Formula (7),

the approximate weight of the girder $= \dfrac{50 \times 50}{700} = 3.57$ tons, or about
and the total load, in round numbers, is 107 000 lb. This, of cours
formly distributed.

* From "Compound Riveted Girders," by W. H. Birkmire.

Second Step. The Flange-Area. The next step is to determine the flange-ea. Before this can be done, however, the width and depth of the girder st be decided. As it is desirable to keep the girder as shallow as possible, nsistent with good engineering, the case will be considered an exceptional e and the depth of the web-plate will be made 36 in. which is about one-teenth the span and a little less than the usual limit.

As the girders are braced sidewise by the floor-joists, it will not be necessary make the width of the flange-plates one-twentieth the span of the girder, d it may be made 12 in width. The flange-area may be determined by rmula (1), page 683, and is

$$A = M_{\max}/dS$$

$$\text{flange-area (sq in)} = \frac{\text{maximum bending moment (ft-tons)}}{\text{depth of web (ft)} \times S \text{ (tons per sq in)}}$$

The maximum bending moment for a uniformly distributed load on a simple m is $M_{\max} = Wl/8$ (Case V, page 326), or in this particular case, 53.57 s × 50 ft/8 = 334.8 ft-tons.

The value of S * has varied in the handbooks from 6 to 8 tons, depending n varying conditions and upon the judgment of engineers. A value of S tons or 16 000 lb per sq in is the requirement of the new New York Building de, and of the codes of most cities. In this example 14 000 lb per sq in is med for S.

bstituting this value in the formula gives for the net area of either flange, 8/(3 × 7) = 16 sq in.

he upper flange may now be designed. For a girder of this size and loaded is way, it will be advisable to try two 5 by 3½ by 7/16-in angles, with the legs horizontal.† The sectional area of these angles (Table XI, page 363) 06 sq in which leaves 9 sq in for the area of the flange-plates. Dividing this 2-in, the width of the flange, gives ¾ in for the total thickness of the plates, h may be made up of two ⅜-in thick plates. Of course, any other combina- of plates and angles having an area of cross-section of 16 sq in will fulfill conditions of the problem, the selection in all cases depending upon the ment and experience of the designer. Note, also, that no part of the web een included in the flange-area although it would be safe to include one- of it. This also is a matter of individual opinion.

the lower flange is in tension, the rivet-holes should be deducted in order tain the net area. Assuming that ¾-in diameter rivets are used, it will ted that the greatest loss of section is by two rivet-holes opposite each connecting the angles with the plates of the bottom flange. From Table I, 02, the area of two ¾-in rivets in a ¾-in plate is 1.31 sq in, and in a plate, the same thickness as that of the angles, it is 0.76 sq in. The sum e thicknesses is 2.07 sq in, which must be added to the net area of the flange-plates, 16 sq in, making 18.07 sq in for the gross area of the lower

, in Chapter XV, paragraphs and foot-notes, page 603, relating to fiber-stresses ling for riveted beam girders, etc.

the flange-angles of plate girders the 5 by 3½-in size is most commonly used, flange-plate is 12 in wide, and 6 by 4-in angles when the flange-plate is over 12 in For box girders 5 by 4, 5 by 3½, 4 by 3½ and 3½ by 3½-in are common sizes; very heavily loaded girders, requiring two rows of rivets in the web-leg, 6 by s are often used. For most riveted girders, in which only one row of rivets is the short leg is riveted to the web, so as to bring most of the material as far from ral axis of the girder as possible. The minimum thickness of flange-angles ⅜ in, and the maximum thickness for ordinary loads is ¾ in.

flange-plates. This additional area may be obtained by increasing the thi ness of the plates to ½ in.

The flanges will then be made up as follows:

Upper flange:	Two angles 5 by 3½ by 7/16-in	= 7.06 sq in, gross area
	Two plates 12 by ⅜-in	= 9.00 sq in, gross area
	Total	16.06 sq in, gross area
Lower flange:	Two angles, 5 by 3½ by 7/16-in	= 7.06 sq in, gross area
	Two plates, 12 by ½-in	= 12.00 sq in, gross area
	Total	= 19.06 sq in, gross area

Third Step. The Length of the Flange-Plates. To determine this it necessary to plot the bending-moment diagram shown in Fig. 12. The bendin

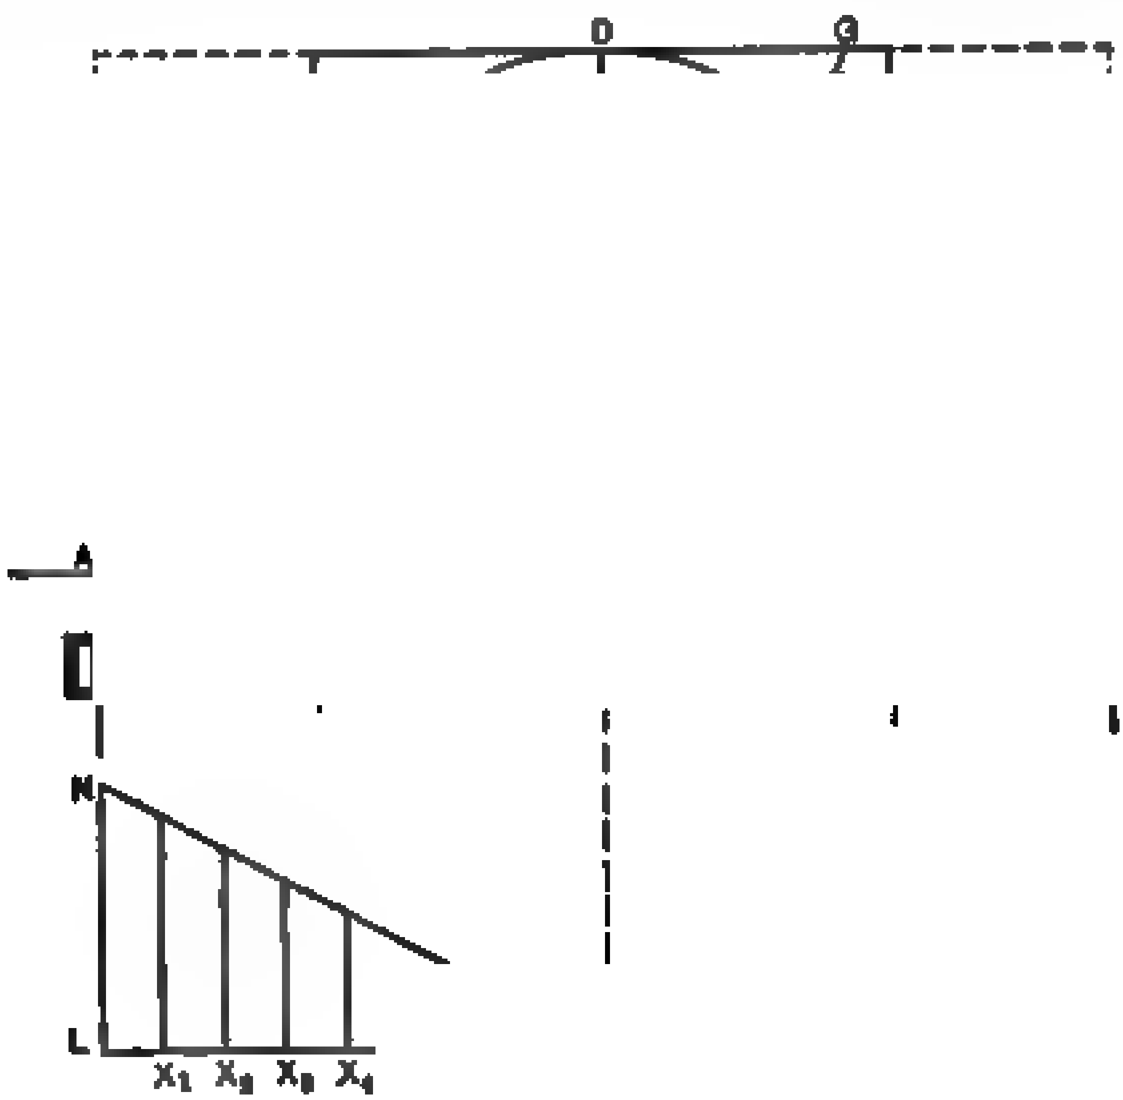


Fig. 12. Diagrams for Bending Moments and Vertical Shears. Example 2

moment diagram for a girder under a uniformly distributed load is bounded a parabola having a height over the middle of the girder equal to the maximu bending moment. From the middle point *C*, of a horizontal line *AB*, at a convenient scale, lay off a vertical line *CD*, equal to the maximum bend moment, 334.8 ft-tons. Construct the parabola *ADB* (see page 79); then bending moment at any other point, as *E*, is equal to the ordinate *EF* at that point, measured to the same scale.

To find the theoretical length of the flange-plates of the lower flange, inclose the bending-moment diagram in a rectangle and from any convenient point, such as C, lay off any line CG, equal to the total flange-area, 19 units in length, and at such an angle that the upper end G will lie on a horizontal line drawn through D. Divide the line CG into three parts, CH representing the sectional area of the angles, equal to 7 units, and HI and IG representing the sectional area of the two plates, equal to 6 units each. Draw horizontal lines through H and I; then the line JJ will represent the theoretical required length of the second or upper flange-plate and the line KK the length of the first or lower flange-plate. In practice, however, the plates are usually extended beyond the points J and K on each side as an additional factor of safety, a distance sufficient to take enough rivets to transmit at least one-third the resistance of the plate. It is also customary to make the first or lower flange-plate the full length of the girder as it greatly stiffens the angles and adds but a small amount to the cost. Theoretically the length of the flange-plates of the top flange would be less than the length of the plates of the lower flange, because the flange-area of the top flange is less than that of the lower flange; but they are usually made the same length.

Fourth Step. The Web. Webs are proportioned to resist the shear. The maximum shearing-stress in a girder uniformly loaded is equal to either reaction, which in this case is one-half the total load, or 53 500 lb. As the girder is 3 ft deep, this small shear would require a very thin section, thinner than the minimum thickness for webs, which is ⅜ in. From Table II, page 703, it is seen that the shearing resistance of a ⅜ by 36-in web-plate is 135 000 lb, which is greatly in excess of the actual shear.

Fifth Step. The Stiffeners. As before explained, stiffeners will be required whenever the vertical shear exceeds the safe resistance of the web to buckling. The vertical shear is 53 500 lb and the resistance to buckling may be found from Table III, page 705. This, for a ⅜ by 36-in web with two ¾-in rivets is found to be 31 560 lb; hence stiffeners will have to be used. As stated under Buckling of Web, page 686, the spacing of stiffeners is more a matter of judgment and experience than of exact calculation, and for this a shear-diagram, also shown in Fig. 12, is of great assistance. It may be constructed as follows: On a horizontal line LM, lay off to any convenient scale vertical lines LN and MP, each representing 53 500 lb. Connect the points N and P; then the vertical shear at any point is equal to the ordinate at that point, measured to the same scale. Thus, at X_1, 3 ft from the left end, the shear is 47 500 lb, at X_2, 6 ft from L, it is 40 500 lb, at X_3, 9 ft from L, it is 34 000 lb and at X_4, 12 ft from L, it is 27 500 lb. As the vertical shear at X_3 is greater than the safe resistance to buckling and at X_4 less, it might be safe to stop the stiffeners at X_4; but as the floor-joists are framed flush, or nearly so, with the top of the girder, and rest upon angles riveted to its web, it will be advisable to put about 3 stiffeners between X_4 and the corresponding point on the right-hand half of the girder. Additional stiffeners should be placed directly over each support, making 15 stiffeners on each side of the girder. These will be made of 4 by 4 by ⅜-in angles.

Sixth Step. The Number and Pitch of the Rivets. First, the number of rivets in the web will be considered. As a rivet is required at the end of each stiffener, it will be necessary to determine the number and spacing of the rivets between each pair of adjacent stiffeners. In the web, the rivets are in double shear. In Tables II and III, pages 418 and 419, values are given based upon unit shearing values of 7 500 and 10 000 and bearing values of 15 000 and 20 000 lb per sq in. (See foot-notes with these tables.) The shearing resistance

of a ¾-in rivet at 10 000* lb per sq in is 4 420 × 2 = 8 840 lb for double she and the bearing value of the same rivet in a ⅜-in plate, at 20 000* lb per sq is 5 630 lb. As the bearing value is the smaller, it will determine the num of rivets required.

The number of rivets from either end of the girder to any point depends u the horizontal flange-stress at that point, and it has been shown that the flan stress is equal to the bending moment divided by the depth of the web. (foot-notes with Equations (5) and (6).) Scaling off the bending moment ab the point X_1 gives 75 ft-tons; hence the horizontal flange-stress is equal to 75/. 25 tons = 50 000 lb. The number of rivets required between this point and left reaction is, from Formula (5), equal to 50 000/5 630 = 10 rivets, which to be spaced in a distance of 36 in, making the spacing 3.6 in. Above X_2 bending moment scales 141.24 ft-tons, the flange-stress is 141.24/3 = 47.08 t or 94 160 lb, and the number of rivets required between X_2 and A is 94 160/5 = 17; but 10 of these are required between X_1 and A, leaving 7 to be pla between X_1 and X_2 in a distance of 36 in making the spacing 5.1 in. At X_3, bending moment scales 197.4 ft-tons, and the flange-stress is 197.4/3 = 65.3 t or 130 600 lb. The number of rivets required is 130 600/5 630 = 24, but 1 these are required between X_2 and A, leaving 7 to be placed between X_2 X_3, making the spacing the same as in the second panel. At X_4 the benc moment scales 243.96 ft-tons, and the flange-stress is 243.96/3 = 81.32 ton 162 640 lb. The number of rivets required is 162 640/5 630 = 30, but 2 these are required between X_3 and A, leaving 6 to be placed between X_3 and in a distance of 36 in, making the spacing 6 in. As this is the maximum spa allowed, it will be used from X_4 to the corresponding point on the oppo right-hand half of the girder. The same number of rivets will be used in flange-legs of the angles as in the web-legs, but they will be spaced so t they will come between those in the web.

The outer flange-plate scales 28 ft 6 in in length in the bending-moment gram, but this length, as before stated, should be increased sufficiently to t enough rivets to transmit at least one-third of the resistance. The area of plate is ½ in × 12 in = 6 sq in, minus the area of two ¾-in rivet-holes, 0.8 in (Table I, page 702), leaving a net area of 5.13 sq in. The resistanc the plate is therefore equal to 5.13 sq in × 14 000 lb per sq in = 71 820 lb. (third of this, or 23 940 lb, must be transferred by rivets placed beyond points JJ. As the rivets in the flange are in single shear, the shearing v of one rivet in single shear, 4 420 lb, will govern. The number of rivets quired, then, is 23 940/4 420 = 6, or 3 in each angle. The spacing of the ri in this panel is 6 in. The plates will therefore be extended 18 in on either of JJ.

* The shearing value of rivets is taken at from 7 000 to 12 000 lb per sq in an bearing value at from 12 000 to 24 000 lb per sq in. The usual values are 10 000 l shear and 20 000 or 24 000 lb for bearing. Values of 12 000 lb for shear and 24 0 for bearing are the requirements of the New York Building Code A bearing other than those of Tables II and III, pages 418 and 419 is purposely used in this exa as it is frequently necessary to use different unit stresses than those from which particular table has been computed. If no other table is at hand for the values based some particular rivet bearing-stress. Tables II and III, pages 418 and 419, be used and the new value found by proportion; or the bearing-stress ca found by multiplying the product of the diameter of the rivet and the t ness of the web by the new unit stress. In this example, Table III, page gives, for 18 000 unit stress, 5 060 lb for bearing; 10/9 of this gives 5 6 for a 20 000 unit stress. Also, ⅜ in by ¾ in by 20 000 lb per sq in = lb.

Splices. As the total length of the girder is but 53 ft, it will not be necessary to splice the webs or the flanges, because the extreme length of a ⅜ by 36-in plate is 110 ft and of a 12 by ½-in plate, 90 ft.* It is never necessary to splice angles as they are rolled in lengths up to 90 ft. In very long, deep girders, however, it is sometimes necessary to splice the web, and the joint is sometimes made at the middle, as theoretically there is no vertical shearing-stress in the web

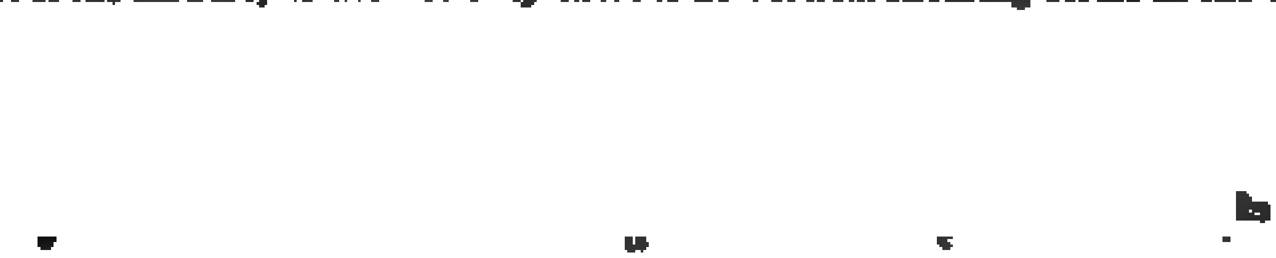

Fig. 13. Splicing of Inner Plate of Bottom Flange of Plate Girder. Example 1

at that point when the load is uniformly distributed. Generally, however, the web is spliced in two places, equidistant from the middle of the girder. The splice is calculated for vertical shear only, the rule being to divide the shear at the splice by the safe shearing value or bearing value of one rivet. This gives the number of rivets required on each side of the splice-plate, unless the maximum pitch is exceeded, when more are added.

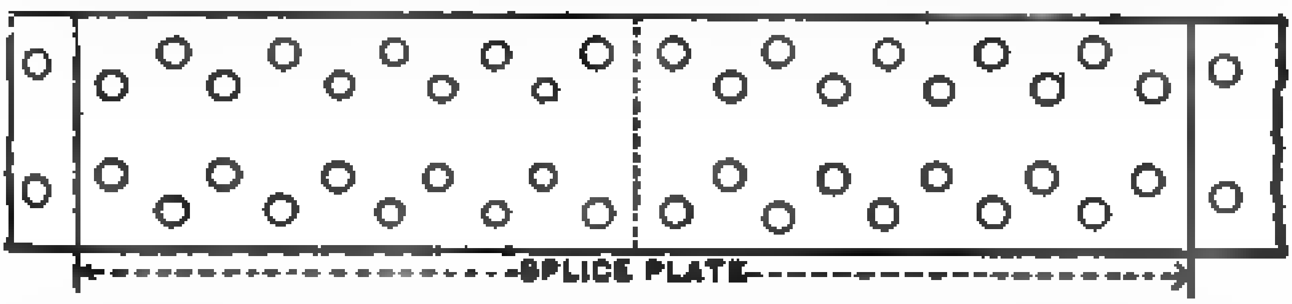

Fig. 14. Plan of Splice-plate. Example 1

Whenever a splice is required in a flange-plate, it should be, if possible, at a point just beyond the end of the plate above it. The joint must be made by fitting to the spliced plate, a plate of the same thickness and of sufficient length to receive a number of rivets on each side of the joint equal to the strength of the plate that is spliced. When the flange is made up of two plates of the same thickness, the simplest method of splicing the inner plate is as shown in Fig. 13.

Let *e* denote the theoretical position of the end of the outer plate, as determined by the bending-moment diagram, and *a* the point to which the plate must be extended to receive rivets of a resistance equal to one-third the strength of the plate. Then let the joint in the inner plate be just over *a* and extend the splice-plate to *b*, or such a distance that it can receive a number of rivets equal in resistance to the strength of one plate.

* Tables of extreme lengths are published in the various handbooks. The above dimensions, for example, are taken from the table on page 111 of Carnegie's Pocket companion.

Fig. 15 shows one end of the girder, drawn according to the foregoing calcu-lations.

The Bill of Quantities for the Girder. The following is a bill of quantitie for the construction of thi girder.

Load: 100 000 lb, uniforml distributed. Span 50 ft Depth 3 ft

Upper flange:
- Two angles, 5 by 3½ b 7/16 in, 53 ft long
- One plate 12 by ¾ in, 5 ft 0 in long
- One plate, 12 by ¾ in, 3 ft 6 in long

Lower flange:
- Two angles, 5 by 3½ b 7/16 in, 53 ft long
- One plate, 12 by ½ in, 5 ft 0 in long
- One plate, 12 by ½ in, 3 ft 6 in long

Web:
- One plate, 36 by ⅜ in, 5 ft 0 in long
- 30 stiffeners, 4 by 4 b ⅜-in angles, 2 ft 11 l long
- 30 filler-plates, 4 by ¼ i 29 in long
- 92 ft 8 in of 4 by 4 b ½-in angles for sup porting floor-joists

Rivets:
- ¾ in in diameter

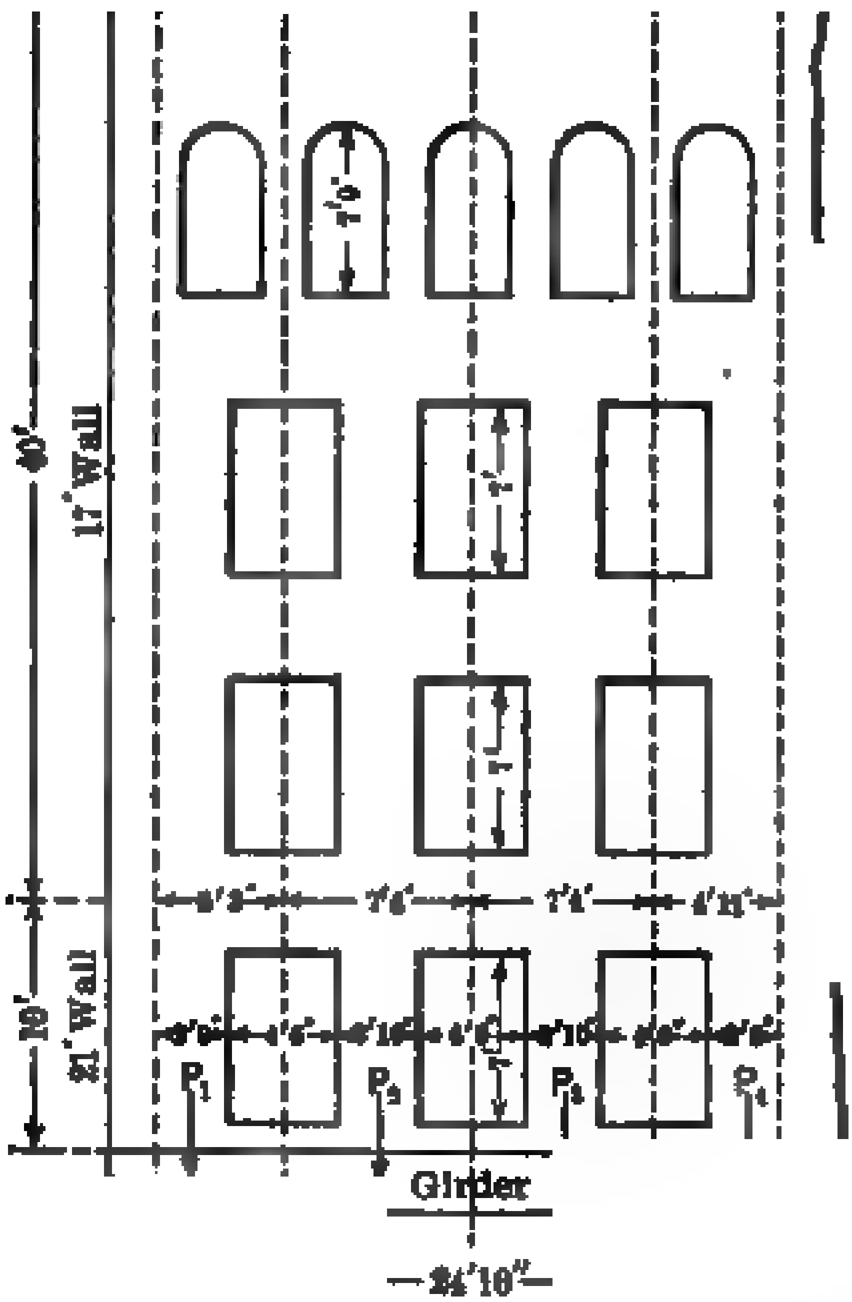

Fig. 16. Box Girder Supporting Brick Wall. Example 2

Example 2. The wall show in Fig. 16 is to be supported b a riveted-steel box girder at th height indicated. It is re quired to design the girder.

First Step. The Load. The first step towards designing the girder is the de termination of the load. The space under the lower windows is too small to dis tribute the weight from the piers uniformly over the girder, so that the only sa assumption is that the weight of the wall between the lines *A* and *B* is conce trated at P_1, the weight of wall between lines *B* and *C* at P_2 and so on. Th floor-joists run across the building, so that only the weight of the wall will b supported by the girder. Allowing 200 lb per square foot of face for the 21- wall, and 165 lb for the 17-in wall, both walls being plastered on the inside:

Load at P_1

$$= \left\{ \begin{array}{l} [5'\,3'' \times 10' - 7' \times 2'\,3''] \times 200 = \ldots\ldots\ldots\ldots\ldots\ldots\ 7\,350 \\ [5'\,3'' \times 40' - (2'\,3'' \times 14' + 3'\,2'' \times 7')] \times 165 = \ldots\ 25\,795 \end{array} \right\} = 33\,145$$

nd at P_2

$$\left\{\begin{array}{l}[7'\,4''\times 10' - 4'\,6''\times 7'\,0''] \times 200 = \ldots\ldots\ldots\ldots\ldots\ 8\,366 \\ [7'\,4''\times 40' - (4'\,6''\times 14' + 4'\,9''\times 7')]\times 165 = \ldots\ldots 32\,354\end{array}\right\} = 40\,720\text{ lb}$$

nd at P_3 = that at P_2 = ... 40 720 lb

nd at P_4

$$\left\{\begin{array}{l}[4'\,11''\times 10' - 2'\,3''\times 7'] \times 200 = \ldots\ldots\ldots\ldots\ldots\ 6\,683 \\ [4'\,11''\times 40' - (2'\,3''\times 14' + 3'\,2''\times 7')]\times 165 = \ldots 23\,595\end{array}\right\} = 30\,278\text{ lb}$$

Total load on girder = ... 144 863 lb

72.4 tons

m Equation (7)

pproximate weight of girder $= \dfrac{W \times l}{700} = \dfrac{72.4 \times 24\frac{5}{6}}{700} = 2.5$ tons, or 5 000 lb

ut one-third of this, or say 1 600 lb, should be added to P_2 and P_3, and 900 lb P_1 and P_4. This will give, approximately, the following loads, applied as in . 17:

$P_1 = 34\,000$ lb $\qquad P_2 = 42\,300$ lb

$P_3 = 42\,300$ lb $\qquad P_4 = 31\,200$ lb

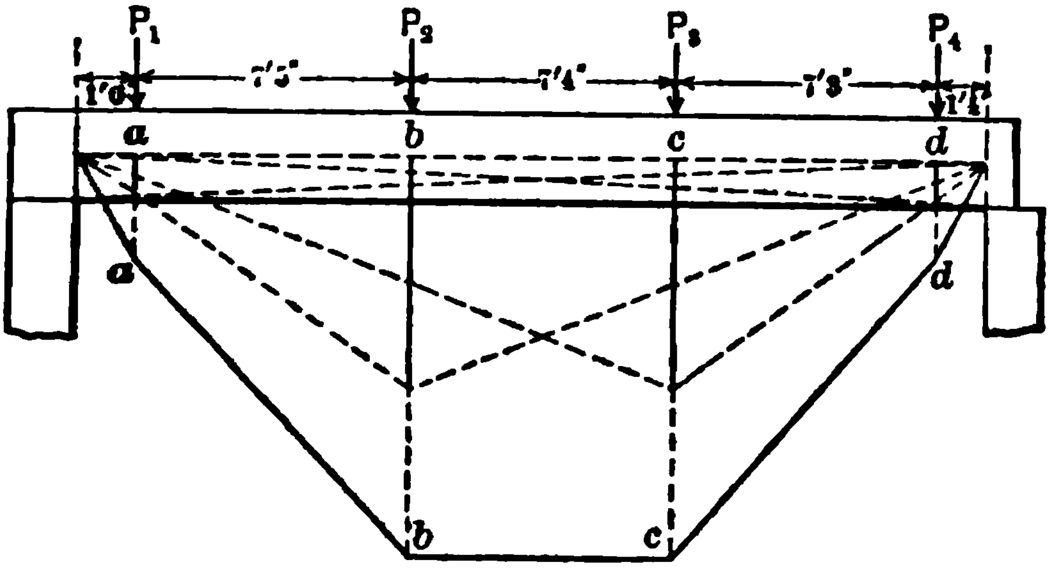

Fig. 17. Diagram for Bending Moments. Example 2

cond Step. The Determination of the Maximum Bending Moment. By s of the formula under Case VI, page 327, the maximum bending moment t-pounds for the loads are found to be as follows:

$$\text{For } P_1,\ M_{\max} = \frac{34\,000 \times 1'\,6'' \times 23'\,4''}{24'\,10''} = 47\,980 \text{ ft-lb}$$

$$\text{For } P_2,\ M_{\max} = \frac{42\,300 \times 8'\,11'' \times 15'\,11''}{24'\,10''} = 242\,000 \text{ ft-lb}$$

$$\text{For } P_3,\ M_{\max} = \frac{42\,300 \times 16'\,3'' \times 8'\,7''}{24'\,10''} = 237\,900 \text{ ft-lb}$$

$$\text{For } P_4,\ M_{\max} = \frac{31\,200 \times 1'\,4'' \times 23'\,6''}{24'\,10''} = 39\,420 \text{ ft-lb}$$

ting these moments to a scale, as explained for Fig. 15, page 329, the ng-moment diagram shown in Fig. 17 * is obtained. The maximum bend-

he bending moments in this diagram are drawn to a scale of about 400 000 ft-lb ch.

ing moment is at P_2, over the longest ordinate bb and where the vertical s is zero, and is equal to the length of the ordinate bb, which scales 418 000 or 209 ft-tons.

Third Step. The Determination of the Flange-Area and the Length of Cover-Plates. Before these can be determined, the depth of the web-must be decided. As there is nothing to limit the depth of the girder, it be made about one-tenth of the span, or 30 in. Then by Formula (1), 683, $A = M_{max}/dS$, and using 14 000 lb or 7 tons per sq in for S,

$$\text{the gross area of upper flange} = 209/2.5 \times 7 = 12 \text{ sq in}$$

As the thickness of the wall to be supported is 21 in, the flange-plate mu at least 20 in wide and not less than ⅜ in thick. The sectional area of by 20-in plate is 7½ sq in, leaving 4½ sq in to be made up by the a The sectional area of two 5 by 3½ by 7/16-in angles is 7.06 sq in (Table page 363), which leaves a small excess for the lower flange. For rivets in diameter, the loss in area due to two rivet-holes in a ⅜-in plate is (Ta page 702) 0.65 sq in and in a 7/16-in plate, the thickness of each angle, 0.76 making 1.41 sq in in all, for which the excess in the angles is more than cient. The width of the flange being more than one-twentieth the span m lateral support unnecessary.

Fourth Step. The Webs and Stiffeners. The maximum shear is equal t maximum reaction which in this case is obviously equal to the left rea Taking the center of moments at the right reaction, the equation of momen

$$R_1 \times 24.83' = (17 \text{ tons} \times 23.33') + (21.15 \text{ tons} \times 15.91') + (21.15 \text{ tons} \times 8.$$
$$+ (15.6 \text{ tons} \times 1.33')$$

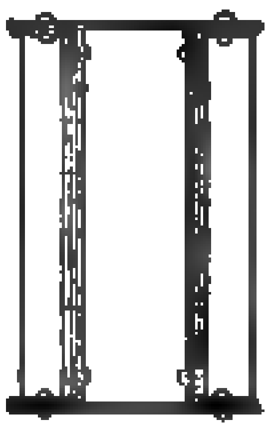
whence $24.83 \times R_1 = 935.3215$ ft-tons and $R_1 = 37.669$ tons, or 75 338 lb. that the loads have been changed from pounds to tons, for convenience in ing the calculations. As this box girder has two webs, the maximum sh each web will be 37 669 lb. The thinnest web permissible is ⅜ in thick. Table II, page 703, the resistance of a ⅜ by 30-in web-plate to sheari 112 500 lb, so that the webs are amply safe in resisting vertical shear. Table III, page 705, the safe resistance to buckling, deducting for two rivets, is 33 830 lb. As this is less than the maximum shear, stiffener be used, placed 2 ft 4 in from each support, with five between them, m the spacing about 3 ft 4 in on centers. Two others will be placed over support. 4 by 4 by ⅜-in angles will be sufficient for the stiffeners.

Note. If the loads were really concentrated at the points P_1, P_2, et from columns or girders, it would be necessary to place stiffeners at eac of these points and two in each of the intermediate spaces, but as the loads are partly distributed it will be better to space them as first planned

Fifth Step. The Number and Pitch of the Rivets. The rivets in the legs and flange-legs of the angles are in single shear. From Table III, 419, the shearing value of a ¾-in rivet in single shear at 10 000 lb per s 4 420 lb, and the bearing value in a ⅜-in plate at 18 000 lb per sq in is 5 Hence the shearing value will govern. The number of rivets required de upon the flange-stress, which is equal to the maximum bending m divided by the depth of the girder. (See Formula (1), page 683.) The b moment at P_1, found by moments or graphically by scaling off the or aa, Fig 17, is 56.5 ft-tons.* This, divided by the depth 2.5 ft, gives 22.

* This may be found, also, by taking P_1 as the center of moments and mult $R_1 = 37.669$ tons by the lever-arm 1½ ft. The result is 56.5 ft-tons. The b moments at the other loads may be determined by taking, in each case, the al sum of the moments of the external vertical forces on either side of each point con

..s 300 lb, for the flange-stress, or 22 600 lb for each web. The number of ..ts, therefore (Formula (5), page 687) is 22 600/4 420 = 6. The distance .. P_1 to the left reaction is 18 in, which makes the spacing 3 in. The ..e-stress at P_2 is 209.88 ft-tons/2.5 ft = 83.95 tons, or 167 900 lb, and one-.. of this is 83 950 lb. The number of rivets therefore is 83 950/4 420 = 19. .. 6 of these are required between P_1 and the left reaction, leaving 13 to go ..een P_1 and P_2, a distance of 89 in, making the pitch about 6.9 in. As .. exceeds the maximum allowable pitch, the rivets will be spaced 6 in on ..ters between P_1 and P_2, and between P_2 and P_3. The spacing on the right-..d end of the girder will be made the same as that on the left. Some details ..e girder are shown in Fig. 18.



..irder. Example 2

.. **Details and Bill of Quantities for the Girder.** The loads, dimensions, size, ..er of pieces, etc., for the girder are given in the following summary:

..ds: 34 000 lb, 1 ft 6 in from left support. Span: 24 ft 10 in
42 300 lb, 8 ft 11 in from left support Depth: 30 in
42 300 lb, 8 ft 7 in from right support
31 200 lb, 1 ft 4 in from right support
Both flanges: Four angles, 5 by 3½ by 7/16 in, 27 ft 6 in long
One plate, 20 by ¾ in, 27 ft 6 in long
..wo webs: ⅜ by 30 in, 27 ft 6 in long
Twenty-two stiffeners: 4 by 4 by ⅜ in, 29¼ in long
Twenty-two filler-plates: 4 by 7/16 in, 23 in long
..ivets: ¾ in in diameter

..ple 3. What are the dimensions of a box girder, 40 ft in span, required to ..rt the following loads? 90 tons from a column, 8 ft from the left support; ..s from a column, 12 ft from the right support; and a masonry pier, 10 ft ..gth, beginning 10 ft from the left support and weighing 4 tons per running (See Fig. 19.)

.. **Step. The Determination of the Reactions, Shears and Bending Mo-..** To find either reaction, the center of moments is taken at the other ..on. The equation of moments for the left reaction is, therefore, taking the ..f moments at the right reaction,

$$40\,R_1 = (90 \text{ tons} \times 32 \text{ ft}) + (40 \text{ tons} \times 25 \text{ ft}^*) + (75 \text{ tons} \times 12 \text{ ft})$$

..hich

$$40\,R_1 = 4\,780 \text{ ft-tons and } R_1 = 119.5 \text{ tons}$$

..onsidering the moments of forces, distributed loads are treated as if they were ..trated at their centers of gravity.

In like manner, the equation of moments for the right reaction is

$$40\,R_2 = (75 \text{ tons} \times 28 \text{ ft}) + (40 \text{ tons} \times 15 \text{ ft}) + (90 \text{ tons} \times 8 \text{ ft})$$

from which

$$40\,R_2 = 3\,420 \text{ ft-tons, and } R_2 = 85.5 \text{ tons}$$

The greatest vertical shear V_1 is equal to the greater reaction, whic[h is] 119.5 tons. The shear-diagram (Fig. 19) may be constructed by laying o[ff]

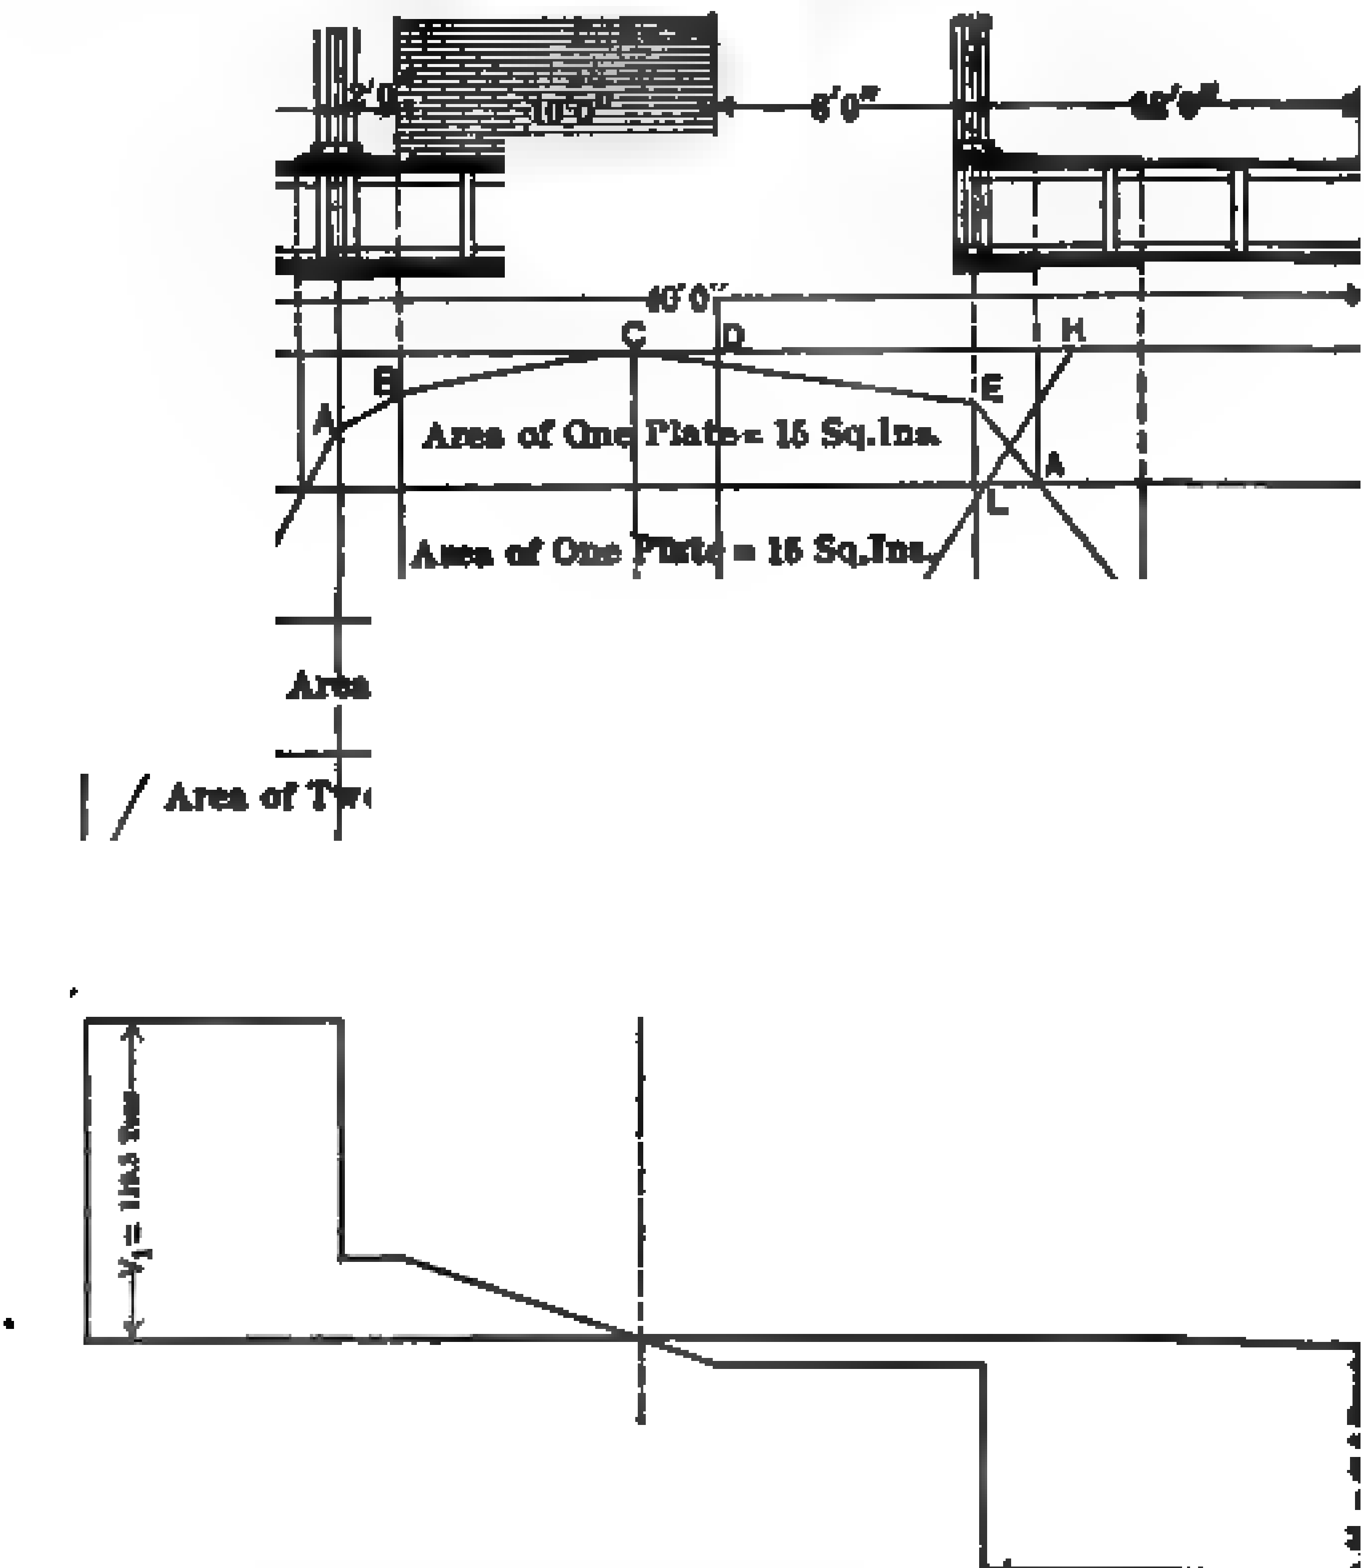


Fig. 19. Elevation of Box Girder and Diagrams for Bending Moments and V[ertical] Shears. Example 3

any convenient scale an ordinate equal in length to 119.5 tons. Immed[iately] at the right of point 1, under the left column, the shear is equal to 119.5 – [90 =] 29.5 tons. It is the same at point 2, the left end of the wall. At point [3, the] right end of the wall, the shear is 119.5 – 90 – 40 = – 10.5 tons, showing t[hat the] shear passes through zero somewhere between 2 and 3, which is the p[oint of] maximum bending moment. This point, X, is by scaling the shear-dia[gram] 17.4 ft from R_1. It is over the point of intersection of the slanting l[ine]

e shear-diagram, with the horizontal line of reference. This slanting line drawn from the top of the shear-ordinate for point 2 to the bottom of the ar-ordinate for point 3. Just at the right of point 4, the shear is 119.5 − − 40 − 75 = −85.5 tons, the same as the right reaction. The point X, of no ar and maximum bending moment, may be found, also, as follows: At the t of point 2 the shear is 29.5 tons. One foot to the right of 2 it is 29.5 s − 4 tons = 25.5 tons. Two feet to the right of 2 it is 29.5 − 8 tons = .5 tons, etc. Therefore, since the shear decreases at the rate of 4 tons per ot, it will be zero at 29.5/4 or 7.4 ft at the right of 2, or 17.4 ft from R_1.

The maximum bending moment is at X, the point of no shear. The equation moments, considering the forces to the left of X, is

$$M_{max} = (119.5 \text{ tons} \times 17.4 \text{ ft}) - (90 \text{ tons} \times 9.4 \text{ ft}) - (4 \text{ tons} \times 7.4 \text{ ft} \times 7.4 \text{ ft}/2)$$

ft/2 is the distance from X to the center of gravity of the wall-load to the t of X, and is the lever-arm of that load, considered as a vertical downward ce concentrated in a single line of action. Hence

$$M_{max} = 2\,079.3 - 846 - 109.5 = 1\,123.8 \text{ ft-tons}$$

The bending-moment diagram may be constructed by laying off at X, at any venient scale, an ordinate XC equal to 1 123.8 ft-tons in length. It is neces- y to find the bending moment at other points, since the bending-moment gram cannot be plotted, as in the previous examples, because the uniform d is not distributed over the entire girder. The other critical points are 1, 3 and 4.

$$M_1 = (119.5 \text{ tons} \times 8 \text{ ft}) = 956 \text{ ft-tons}$$

$$M_2 = (119.5 \text{ tons} \times 10 \text{ ft}) - (90 \text{ tons} \times 2 \text{ ft}) = 1\,015 \text{ ft-tons}$$

$$M_3 = (119.5 \text{ tons} \times 20 \text{ ft}) - (90 \text{ tons} \times 12 \text{ ft}) - (40 \text{ tons} \times 5 \text{ ft}) = 1\,110 \text{ ft-tons}$$

$$M_4 = (119.5 \text{ tons} \times 28 \text{ ft}) - (90 \text{ tons} \times 20 \text{ ft}) - (40 \text{ tons} \times 13 \text{ ft}) = 1\,026 \text{ ft-tons}$$

y laying off ordinates at these points equal by scale to the respective bending ments; drawing straight lines from R to A, the extremity of the ordinate ugh 1, and from A to B; drawing curved lines from B through the points nd D; and connecting D and E and E and R_2 by straight lines; the bending- ment diagram $R_1ABCDER_2$ may be constructed.

econd Step. The Webs. As stated on page 683, it is considered safe by y engineers to include one-sixth of the web-area in the flange-area, and will be done in this example. The web, therefore, must be designed first. there is nothing to limit the depth of the girder, it will be made 3 ft deep, t one-twelfth the span. The greatest vertical shear is equal to the greater ft reaction, 119.5 tons. Since the girder carries a brick wall, it must be of ox type, and hence the vertical shear on each web is 59.75 tons. A ½ by web will be tried first. Its area is 18 sq in, from which must be deducted ss in area due to the rivet-holes for the rivets through the stiffeners. The will be placed the maximum distance on centers, making six in each er. Because of the concentrated loads near the reactions more rivets will quired, and in order to avoid a close spacing, ⅞-in rivets will be used. Table I, page 702, the sectional area to be deducted for a ⅞-in rivet in a plate is 0.50 sq in; hence the net area of the web is 18 − (6 × 0.50) = 15 and its shearing resistance, at 10 000 lb or 5 tons per sq in (Table II, page is 15 × 5 tons = 75 tons, which is 15.25 tons in excess of the 59.75 tons ed.

d Step. The Flange-Area. From Formula (1), page 683,

$$\text{the flange area, } A = M_{max}/dS = \frac{1\,123.8}{3 \times 7} = 53.5 \text{ sq in}$$

As the girder has no lateral support, the flange-width should be not less than (twentieth the span, which will make it 2 ft.

The upper flange may be proportioned as follows:

One-sixth of net section-area of two webs =	5.00 sq in
Two 5 by 5 by 9/16-in angles,* with section-area =	10.62 sq in
Three 9/16 by 24-in plates, with section-area of 13.50 sq in each =	40.50 sq in
Total section-area of upper flange =	56.12 sq in

To proportion the lower flange, allowance must be made for the loss in area due to two rivet-holes.

From Table I, page 702, the area of two 7/8-in rivet-holes in a 9/16-in plate (thickness of angles) =	1.12 sq in
Area† of two rivet-holes in three 5/8-in flange-plates =	3.75 sq in
Total rivet-area =	4.87 sq in

Hence the gross section-area of the lower flange must be $53.5 + 4.87 = 58$ sq in.

This may be made up of

One-sixth of net section-area of two webs =	5.0 sq in
Two 5 by 5 by 9/16-in angles, with section-area =	10.62 sq in
Three 5/8 by 24-in plates, with section-area of 15 sq in each =	45.00 sq in
Total section-area of lower flange‡ =	60.62 sq in

The length of the flange-plates is determined from the bending-mo diagram. Draw a horizontal line through *C* (Fig. 19) and at any point, lay off to any convenient scale and angle, a line $3\,H = 60.62$ units in le with its upper extremity on the horizontal line *FG* drawn through *C*. D this line into five parts: $3\,I$, containing 5 units for the web-area; *IJ*, 10.62 for the angles; and *JK*, *KL* and *LH* of 15 units each, for the three plates. horizontal lines through the points *I*, *J*, *K* and *L* as shown. The horiz intercepts of these horizontals in the bending-moment diagram will giv theoretical lengths of the flange-plates. For practical considerations, the plate is always carried the full length of the girder and the other plates a tended beyond the intersection-points on either side, a distance sufficie take enough rivets to transmit at least one-third of the resistance of the The resistance *AS*, of the outer plate is 15 sq in × 14 000 lb per sq in = 210 o One-third of this, or 70 000 lb, must be resisted by rivets placed beyon points *AA*. From Table III, page 419, at 10 000 lb per sq in, the sh value of a 7/8-in steel rivet in single shear is 6 010 lb and in a 5/8-in plate its be value at 18 000 lb per sq in is 9 820 lb. Hence the number of rivets requi 70 000/6 010 = 12, or 6 on each side. With a 2-in pitch this would length plate 12 in at each end. The outside plates in this particular girder wo extended far enough to pass beyond the base of the column on the left s the girder.

* Angles with equal legs are selected because the same number of rivets will quired in both legs, as they are all in single shear, and large angles are selected b the rivets will have to be staggered, owing to the concentrated loads being placed the ends of the girder.

† Since 9/16-in plates are selected for the upper flange, it is reasonable to suppo 5/8-in plates will be necessary for the lower flange.

‡ Both flange-areas are made slightly in excess of the requirements, because example one-sixth of the web-area is included.

Fourth Step. The Stiffeners. From Table III, page 705, the safe buckling value of a ½ by 36-in plate with two ⅞-in rivets is 62 320 lb, and as this is much less than the shearing value, stiffeners must be used. The stiffeners under the concentrated loads may be considered as short struts in direct compression. Assuming that 4 by 4 by ½-in angles are used for the stiffeners, the safe load from Table XV, page 502, is over 20 tons. The greatest concentrated load is 90 tons, and hence four stiffeners will be placed under each column. Four more will be placed at each bearing, as shown in Fig. 19, four on each side, between the columns, about 4 ft on centers; and two on each side, between the columns and the bearings, making 15 on each side, or 30 in all.

Fifth Step. The Number and Pitch of the Rivets. In a box girder, the rivets are in single shear. The shearing value of a ⅞-in rivet at 10 000 lb per sq in is, from Table III, page 419, 6 010 lb, and its bearing value at 18 000 lb per sq in, in a 7/16-in plate, the thinnest outside plate, is 6 880 lb; hence the shearing value will govern.

The number of rivets depends upon the horizontal flange-stress, which is equal to the maximum bending moment divided by the depth of the girder (Formula (1), page 683). M at 1 = 956 ft-tons, and the horizontal flange-stress = 956/3 = 319 tons, or 638 000 lb. From Formula (5), page 687, the number of rivets required = 638 000/6 010 = 106, or 53 on each side. These are to be placed in a distance of 8 ft, or 96 in, which makes the pitch about 1.8 in. As this is less than the minimum pitch, 2⅝ in, or three diameters, the rivets will have to be staggered. Hence the justification for selecting large angles with equal legs for this paricular girder. At X the horizontal flange-stress = 1123.8/3 = 374.6 tons, or 749 200 lb, and the number of rivets is 749 200/6 010 = 124, or 62 on each side; 53 of these, however, are required between R_1 and 1, leaving 9 to be placed between 1 and X, a distance of about 9 ft. As the resulting pitch will exceed the maximum pitch, they will be placed 6 in on centers between 1 and X. At 4 the horizontal flange-stress = 1 026/3 = 342 tons, or 684 000 lb. The number of rivets is 684 000/6 010 = 112, or 56 on each side, to be spaced in a distance of 12 ft, or 144 in, making the spacing 2.5 in. Between 4 and X the maximum pitch will be determined as before.

Sixth Step. The Weight of the Girder. So far, no account has been taken of the weight of the girder. The practice is to neglect this weight when the maximum bending moment due to it alone is less than 10% of the maximum bending moment due to the loads. From Formula (7), page 688, the weight of the girder = 205 × 40/700 = 12 tons. From Case V, page 326, the maximum bending moment due to it = 12 × 40/8 = 60 ft-tons. As this is much less than 10% of 1123.8 ft-tons, the maximum bending moment due to the loads, it may be neglected. Had it been otherwise, the weight would have to be considered as an additional uniformly distributed load over the entire girder and a new bending-moment diagram drawn.

Further Data on Riveted Girders. By applying the principles illustrated in the preceding examples it is possible to compute the necessary dimensions and details for riveted girders under any conditions of loading. If further examples are desired, the reader is referred to "Compound Riveted Girders," by William Birkmire, in which different examples of loading are fully worked and explained, and also to other recent treatises on this subject.

Detail Drawings and Stress-Diagrams of one of the earlier heavy plate girders used in building-construction are published in the Engineering Record of Dec. 28, 1895. This girder is one of six plate girders used in the construction of Tremont Temple, Boston, Mass., Blackall & Newton, architects. The girder is 75 ft long between centers of columns, 6 ft 1 in deep, with flanges 28 in

wide, and is calculated to support distributed and concentrated loads ag gating 497.5 tons. The single web-plate is 64¾ in deep, and ⅞ in thick at ends; the flanges are 4½ in thick at the middle of the girder; and the fla angles are 6 by 8 by 1 in. Since that time there have been erected for man the large buildings a number of riveted girders of very great size and stren and details of their construction may be found in the engineering and archi tural periodicals.

6. Tables Used in the Design of Plate and Box Girders

Tables I, II, III and IV contain data usually required for the design of p and box girders to satisfy all but the most unusual conditions.

Table I.*† Sectional Area in Square Inches to be Deducted from Plates Angles for Rivet-Holes

moment by the PERMISSIBLE UNIT STRESS FOR FLEXURE in pounds per sq inch. The SPACING OF THE RIVETS, the number and position of the STIFFEN the LENGTH OF THE FLANGE-PLATES, if more than one are needed, and the IN FLANGE-AREA and WEB-AREA due to the punching of the RIVET-HOLES, be determined in each case by the rules already given. The weights of rivets and stiffeners are not included.

As an illustration of the use of these elements or properties, in Exampl the total load on the girder is 107 000 lb, making each end-reaction 53 50 The maximum bending moment is 334.8 ft-tons, or 8 035 000 in-lb. The sec modulus $I/c = M/S = 8\,035\,000/14\,000 = 574$. The depth of the girde limited to 36 in. Looking up the properties of 36-in girders in Table IV, 709, it is seen that a ⅜-in web is more than sufficient to resist the reaction. The nearest section-modulus to 574 is 567.2, that of a girder posed of a 36 by 7/16-in web, 5 by 3½ by ½-in angles, and 12 by ½-in fl plates. In working out the problem in detail it was found that the g required 5 by 3½ by 7/16-in angles and two 12 by ½-in flange-plates to pensate for the loss of area due to the punching of the rivet-holes. (See 219 and 710.)

Table IV is based upon an extreme fiber-stress for flexure of 16 000 lb per and gross sections are used in determining the values given. The attenti readers is called to the two methods of plate and box-girder design: (1) th using the plate-girder formula (page 683), and (2) the one using the sec modulus (pages 703 and 704, and 706 to 716). It is customary, also, to into account the tendency of the compression-flange of the girder, if long bet lateral bracings, to buckle or fail as a column; and the permissible reduced fi stress is determined by column-formulas.

Table III.* Safe Buckling Values of Web-Plates

SAFE UNIT BUCKLING VALUE IN POUNDS PER SQUARE INCH

$$\text{Calculated by formula† } S_b = \frac{10\,000}{1 + \dfrac{d^2}{3\,000\,t^2}}$$

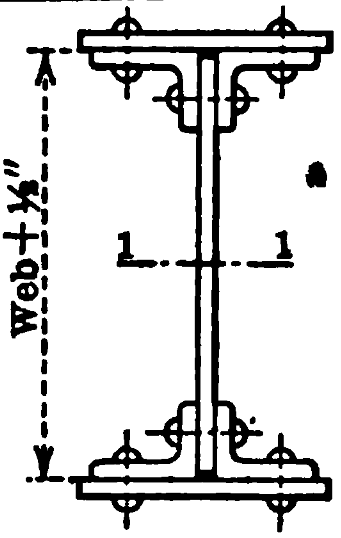
* For explanation of tables, see Subdivision 4, page 688.
† See in Chapter XV the paragraphs and foot-notes, pages 568 and 569, relating tc web-buckling of I-beams. The formula for the above table is the formula that was [used] in the Passaic Steel Company's Manual, and as the values computed by it vary but [little] from those deduced by the Cambria formula, Table III is retained as it is.
See, also, page 686, paragraph relating to Safe Resistance of Web to Buckling.

Table IV.* Elements of Riveted Plate Girders



To determine the details of construction of a girder su[itable] able to carry any specified loading, determine the ma[ximum] mum end-reactions in pounds and the maximum bendi[ng] moment in inch-pounds

Select from the table a girder having the desired dep[th] a thickness of web as determined by the maximum en[d] reaction and a suitable section-modulus, determined [by] dividing the maximum bending moment by the permis[si]ble unit bending fiber-stress in pounds per square inc[h]

For limiting conditions, see the pages 702 to 705 a[nd] the first three subdivisions of this chapter

Weights given do not include stiffeners, rivet-heads, [or] other details

CHAPTER XXI

STRENGTH AND STIFFNESS OF WOODEN FLOORS

BY
THOMAS NOLAN
PROFESSOR OF ARCHITECTURAL CONSTRUCTION, UNIVERSITY OF PENNSYLVANIA

The Problems Stated. The problems which are presented in this part of building-construction are, in general, (1) the designing of the joists and girders forming the framework of the floor to safely support the greatest load likely to come upon it, and (2) the determination of the maximum safe load for a floor already built. The first of these problems is the one with which architects and builders more commonly have to deal, and is, therefore, considered first.

Layout of the Floor-Framing. Before any calculations can be made for the sizes of the timbers it is necessary to know the spans of the joists, and, if there are openings in the floor, or the floor-joists have to support longitudinal partitions, a framing-plan should be made, showing the floor-area that will be supported by each joist, and also the position of partitions or special loads. If the floor is to be supported by posts and girders the position of these should also be accurately indicated on the framing-plan. Where the joists are supported entirely by walls or partitions, the spans of the joists will of course be fixed by the plan of the building. When the distance between a wall and a partition is too great for a single span, there may be a question as to the best positions for the posts and girders. When planning a building in which wooden joists are to be used, it is important to keep in mind the general scheme of the floor-framing and particularly the spans. Whenever practicable the spans of wooden joists should not exceed 24 ft. When the distance between the supporting walls exceeds 30 ft, girders should be placed so that the maximum span of the joists will not exceed 24 ft for light buildings nor from 16 to 18 ft for warehouses.

In School Buildings it is desirable to have the rooms at least 27 ft wide, and since in this class of buildings the joists usually have spans of from 27 to 30 ft. For a span of 30 ft, however, 16-in joists should be used, and as these are expensive, and often difficult to obtain, it is much better and more economical to make the schoolrooms 27 by 32 or 34 ft, than to make them 30 ft square. A schoolroom 27 ft wide by from 32 to 34 ft long, with windows on the long side, is economical and satisfactory, as it permits of using 3 by 14-in joists, 28 ft long, and also results in the most satisfactory lighting.

Continuous Joists. When joists are supported by a girder placed so that a 24 or 26-ft joist extends over the two spans, it is always better to have the joists continuous over the girder, as by that construction they make a much stiffer floor. (See Chapter XIX.)

Floor-Loads. Having decided on the arrangement of the joists, and drawn a framing-plan showing the span and the locations of all special timbers, the

next step involves the determination of the loads for which the joists and girders are to be proportioned. Floor-loads are made up of two parts, the weight of the materials composing the floor itself, and the ceiling below, if there is one; and the load liable to be put on the floor. The first is called the DEAD LOAD, and the second the LIVE LOAD. When the SAFE LOAD for a floor is spoken of the live load is generally meant.

Weight of Wooden Floor-Construction. Wooden floors usually consist of (1) beams, commonly called JOISTS,* or FLOOR-JOISTS, (2) one or two thicknesses of flooring-boards, and, in a finished building, (3) a ceiling underneath the joists. In figuring the weight of ⅞-in flooring-boards it will be sufficiently accurate to estimate the weight of a single thickness at 3 lb per sq ft. joists may also be figured at 3 lb per ft, board-measure, with the exception of hard-pine and oak joists, which should be figured at 4 lb per ft, board-measure. The weight of the joists must also be reduced to their equivalent weight per square foot of floor. Thus, the weight of a 2 by 12-in joist is about 6 lb per ft. If the joists are spaced 12 in on centers, this will be equal to 6 lb per sq ft; but if the joists are 16 in on centers there will be but one linear foot of joist to every 1⅓ sq ft, which will be equivalent to 4½ lb per sq ft; and if they are 20 in on centers, the weight will be equal to 3⅗ lb per sq ft; spaced 24 in on centers, the weight will be 3 lb per sq ft. The weight of a lath-and-plaster ceiling should be taken at 10 lb per sq ft, and of a ¾-in wooden ceiling at per sq ft. A corrugated-iron ceiling weighs about 1 lb per sq ft. For stamped steel ceilings, 2 lb per sq ft will cover the weight of the metal and furring. The following table, giving the weight of joists, will be found convenient in figuring the weight of floors:

Table I. Weight of Floor-Joists per Square Foot of Floor

Sizes of joists	Spruce, hemlock, white pine. Spacing in inches, center to center		Hard pine or oak. Spacing in inches, center to center	
	12	16	12	16
in	lb	lb	lb	lb
2×6	3	2¼	4	3
2×8	4	3	5⅓	4
3×8	6	4½	8	6
2×10	5	3¾	6⅔	5
3×10	7½	5⅝	10	7½
2×12	6	4½	8	6
3×12	9	6¾	12	9
2×14	7	5¼	9⅓	7
3×14	10½	8½	14	10½

Weight of Crowds. L. J. Johnson reports† results of some tests to tain the weight of crowds of men, in which he obtained weights of 134.2,

* Some building laws use the term FLOOR-BEAM instead of the word JOIST.

† See Engineering News, April 14, 1904.

1.1 and 156.9 lb per sq ft. The last-mentioned weight was obtained by packing 67 men in a room about 6 by 11 ft in size. Professor Johnson also found that with 50 men in the room, making a load of 122 lb per sq ft, the crowd was compacted "so that a man could elbow his way through it only with perseverance and determined effort."

Superimposed Loads. There is much difference of opinion as to what allowance should be made for the live load. Table II shows the minimum allowance for live loads for different classes of buildings, as fixed by the building laws of the cities mentioned. (See, also, page 149.)

Table II. Minimum Safe Superimposed Loads for Floors, Required by Various Building Laws

Classes of buildings	Minimum live load per square foot of floor					
	Buffalo, 1905	Boston, 1915	Chicago, 1916	Philadelphia, 1914	New York, 1917	St. Louis, 1910
Dwellings	40	50	40	70	40	60
Hotels, tenements and lodging-houses	70	50	50	70	60	60
Office-buildings	70	80	50	100	60*	70*
Buildings for public assembly	100	100	100	120	100	100†
Stores, warehouses and mfg. bldgs	120‡	125‡	100‡	120‡	120‡	150‡

* First floor, 150 lb. † Also school-houses. ‡ And upwards.

It was the opinion of Mr. Kidder that the following allowances for floor-loads, taken in connection with the values given for the safe strength of joists or beams, provide absolute safety with proper allowance for economy.

	Lb per sq ft
For dwellings, sleeping-rooms and lodging-rooms	40
For schoolrooms	50
For office-buildings, upper stories	60
For office-buildings, first story	80
For stables and carriage-houses	65
For banking-rooms, churches and theaters	80
For assembly-halls, dancing-halls and the corridors of all public buildings, including hotels	120
For drill-rooms	150

Live Loads for Stores and Buildings for Light Manufacturing. Floors for ordinary stores, light manufacturing and light storage should be computed for not less than 120 lb per sq ft, and for a concentrated load at any point of ...0 lb.

Live Loads for Dwellings, etc. Floors of dwellings, tenements, lodging-houses and rooms in hotels, are seldom loaded with more than 20 lb per sq ft for the entire area, and a minimum load of 40 lb per sq ft should provide for all possible contingencies.

Live Loads for Office-Buildings. The floors of offices are, as a rule, not m heavily loaded than the floors of dwellings, but the possibilities for increa loads from safes and heavy furniture, and possibly from a more compact cro of people, are greater, so that the minimum floor-load for offices should be so what increased. Some years ago the firm of Blackall & Everett, in Bos found that the average live load in 210 offices, in three prominent office-buildi in that city, was between 16 and 17 lb per sq ft, while the average load for the heaviest office-buildings was 33.3 lb per sq ft. As such loads, however, are a rule unevenly distributed, some portions of the floor being generally m more heavily loaded than others, it would not appear to be safe to use t average to determine the strength of floor-beams and floor-arches, although would probably answer for the columns. There seems to be a considerable diff ence of opinion among the leading architects and structural engineers as to j what allowance should be made for office-floors. Among some of the ear fire-proof office-buildings, for example, may be mentioned the former M Building in San Francisco in which the live loads were assumed at 40 lb per ft for all floors above the first. In the Venetian Building, Chicago, the seco third and fourth floors were calculated for 60, and the upper floors for 35 lb sq ft of live load, while in the Old Colony and Fort Dearborn Buildings Chicago, the live loads on the floor-beams were assumed at 70 lb per sq At the present time (1915), 50, 60, 70, 75, 100 and 150 lb per sq ft are minimum live loads for the design of floors of office-buildings required by building laws of six different cities. C. C. Schneider recommends* for design of floors of office-buildings above the first floor, for the uniform l of the floor-area, 50; for concentrated loads applied at any point of the fl 5 000; and for the uniform load for girders, 1 000; the 50 being in pounds sq ft, the 5 000 in pounds and the 1 000 in pounds per linear foot.

Live Loads for Churches, Theaters and School-Houses. "An allowance 120 lb per sq ft for the live load in churches, theaters and school-houses is m greater than the actual conditions require. The average size of a schoolro is about 28 by 32 ft, and such a room usually contains seats for fifty-six scho and the teacher. Assuming the average weight of each scholar at 120 lb, average live load, including ten visiting adults and the desks and furniture 13 lb per sq ft. Even supposing that the scholars of two rooms were uni for some special occasion, there would be only 22 lb per sq ft; and this is great a load as it is possible to imagine in such a room, as the fixed desks prev the crowding together of the scholars except at the sides of the room. F this reasoning, therefore, 50 lb per sq ft would appear ample for schoolroo As a matter of fact, 3 by 14-in long-leaf yellow-pine joists, 16 in on cen and with a 28-ft span, have been used for school-room floors for years; such beams, if calculated by the formula for stiffness, would support a load of only 43 lb per sq ft. (Table XII, page 643 and Table I, page 7 The minimum floor-space allotted to a single seat in theaters is 4 sq ft, w the average is about 5 sq ft. Assuming the weight of an opera-chair at 3 and of the average adult at 140 lb, a liberal allowance, there results an ave of 44 lb per sq ft of floor. A minimum of 80 lb per sq ft would therefore s to provide for any possible crowding during a panic, except in corridors. the other hand, it has been shown (see Weight of Crowds, page 718) th crowd of able-bodied men may result in a load of about 120 lb per sq ft, this should be the minimum for assembly-halls without fixed desks and also the corridors of all public buildings. For armories, the minimum load sh be increased on account of the vibration."†

* "General Specifications for Structural Work of Buildings," 1910, page 53.
† F. E. Kidder.

The Average Floor-Loads for Stores has also been greatly over-estimated. W. L. B. Jenney found that the average load on the floors of the wholesale warehouse of Marshall Field & Company, in Chicago, was but 50 lb per sq ft, and very few retail stores will average over 80 lb per sq ft. An allowance of 120 lb per sq ft is sufficient for ordinary retail stores, with the possible exception of hardware stores.

Live Loads for Warehouses. Warehouses, on the other hand, may be very heavily loaded, and the floors in buildings intended for the storage of merchandise should be proportioned to the especial class of goods which they are designed to support. Table III, originally compiled by C. J. H. Woodbury,* and to which some additions have been made by the Insurance Engineering Experiment Station and by Mr. Kidder, will be found of assistance in deciding upon the live load to be assumed for warehouse-floors. The weights per square foot are for single packages. If the goods are piled two or more cases high, the weight per square foot of floor will of course be increased accordingly. In fact, the height to which the goods are liable to be piled is a very important consideration in fixing upon the floor-load. In Table III "the measurements were always taken to the outside of case or package, and gross weights of such packages are given."

Methods of Determining the Sizes of Joists, Beams or Girders Required for Any Building. As already explained, the first step is the making of a framing-plan of the floors or enough of it to show any special framing and also the span and floor-area supported by the different joists, beams or girders.

* For pressure of grain in deep bins, see Engineering News, March 10, 1904, pages 2[illegible] and 336, and Dec. 15., 1904.

The second step is to determine approximately the weight of the floor and ce ing, and decide what superimposed load per square foot the floor is to be design to carry. Having done this, the next step is the computing of the requir dimensions of the common floor-joists. For most buildings the size of floo joists required can be readily determined by reference to Tables XIII to XV inclusive, and XXII to XXVI, inclusive, of this chapter. For other floor-loa the sizes of the common joists may be determined by computing the load be supported by a single joist and then, by the formulas or tables in Chap XVI or the formulas in Chapter XVIII, determining the dimensions of the joi to support that load. (See Example 1.) For the floors of all buildings exce stores and warehouses it is recommended that the sizes of the common joi be determined by the formulas for stiffness in Chapter XVIII or the stiffne values in the tables in Chapter XVI, unless one value, only, is given in tab for safe loads, in which case that value may be used. For stores and wa houses the sizes of the joists may be proportioned by the formulas or streng values of the tables in Chapter XVI.

The Dimensions of Special Beams, such as headers, trimmers and beams su porting partitions, and also of the girders, should be determined in the sa way, that is, by comp ing the maximum lo the beam may have support, and then t dimensions of a be that will support th load with safety. T manner of making computations is e plained in the follow examples.

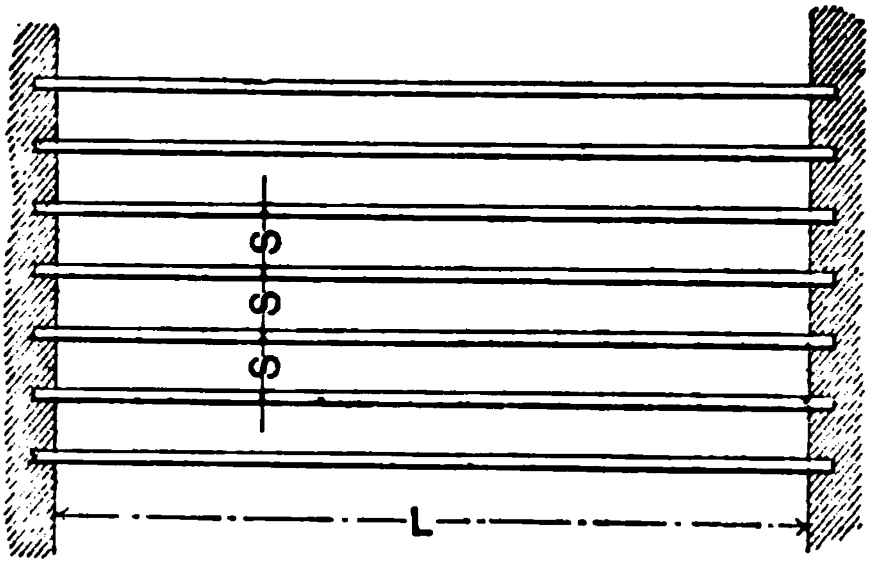

Fig. 1. Plan of Floor-joists

Example 1. The si plest type of floor-fra ing is that shown in F 1, in which all of joists are of the sa span and support equal floor-areas. In such a floor, the FLOOR-AREA su ported by each joist is equal to the span, L, multiplied by the spacing, S, feet. The LOAD on each joist is equal to the FLOOR-AREA multiplied by sum of the dead-loads and superimposed or live loads. To show the appli tion of the above-mentioned formulas and tables we will assume that Fig represents the framing of a floor in a dwelling-house or lodging-house, t $L = 18$ ft, $S = 16$ in or 1⅓ ft, and that the timber is common white pine. T joists are to support a plastered ceiling and a double floor of ⅞-in boar What should be the size of the joists; average quality, conditions not ideal?

Solution. The FLOOR-AREA supported by each joist is 1⅓ by 18, or 24 sq From Table XIII or XXII, pages 737 and 742, for a span of 18 ft, the jo will probably have to be at least 2 by 12 in, and their weight will be about 4½ per sq ft (see Table I, page 718). The plastered ceiling weighs about 10 lb the flooring 6 lb per sq ft, making the total weight of the floor 20½ lb per sq For the superimposed load we should allow at least 40 lb per sq ft (see p 719). This might be greater, if exacted by any particular building law. load on a single joist will, therefore, be, with these assumed unit loads, 60½ by 24 sq ft, or 1 452 lb.

From Table VIII, page 639, we find that the maximum load for a 1

in white-pine joist of 18 ft span is 623 lb; hence to support 1 452 lb will require a breadth equal to 1452/623 = 2⅓ in. Therefore, to comply with the requirements for both strength and stiffness, the joists should be 2⅓ by 12 in. This is not a stock size. Joists 2 by 12 in, 12 in on centers, may next be tried. Each joist must support 1 116 lb, requiring, by Table VIII, page 639, a 1.8 by 12-in joist, determined by the quotient 1 116/623. So that, in this example, white-pine joists of a nominal size of 2 by 12 in and spaced 12 in on centers might be used, although they are slightly under the required depth, as the dressed size is about 1¾ by 11½ in. From Table VI, page 637, the conversion-factor is 1.61, and 623 lb × 1.61 = 1 003 lb which is less than 1 116 lb, the load to be supported. From Tables XIII and XXII, pages 737 and 742, the maximum spans for 2 by 12 in white-pine joists, 12 in on centers, are 19 ft and 18 ft 8 in respectively, according to the assumed value of the modulus of elasticity for white pine. For 3 by 12-in joists, 16 in on centers, the load is 1 506 lb, and 1 506/623 = 2⅖ in. The dressed size is almost 2¾ by 11½ in, the conversion-factor, 2.53, and 623 × 2.53 = 1 576 lb, an amount greater than 1 506 lb. Tables XIII and XXII, again, give 19 ft 8 in and 19 ft in for the maximum spans. Joists 3 by 12, 16 in on centers, are stronger than necessary. If, in this example, the span is made ft, by Table VIII, page 639, for 12-in joists two values for the safe loads are found, and the smaller, stiffness-value, should be used, unless the deflection need not be considered.

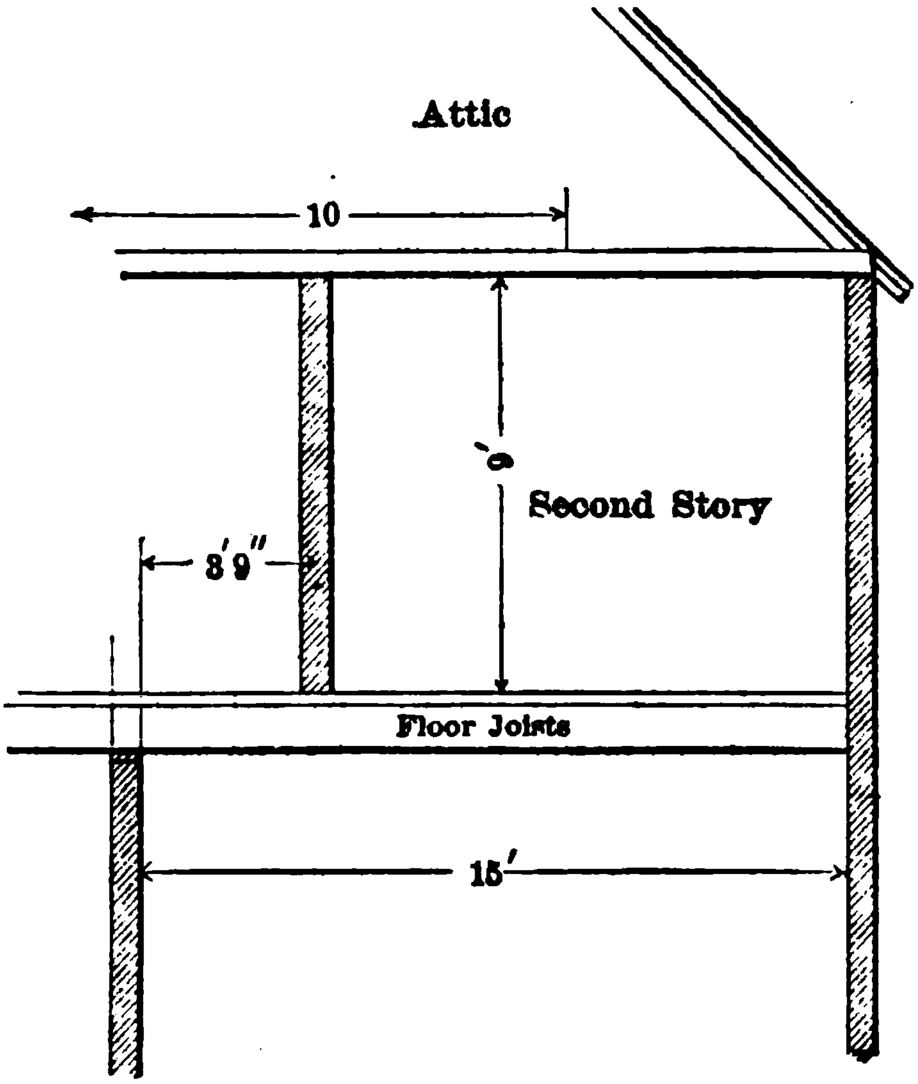

Fig. 2. Section Through Floors and Partitions

Example 2. Fig. 2 shows a partial section of a dwelling, in which the second-floor joists support a plastered partition which also supports the attic joists. What should be the size of the second-floor joists to meet the requirements of STRENGTH, the timber being fair-quality Eastern spruce with a safe fiber-stress assumed to be 700 lb per sq in for flexure? As the effect of a concentrated load, compared with a distributed load, in producing deflection, is not as great as the comparative effect in producing rupture, whenever a beam has a considerable CONCENTRATED load it may be calculated by the formula or tables FOR STRENGTH ONLY. The timber is assumed to be poorly seasoned.

Solution. The first step will be to determine the load on a single floor-joist. We will assume, as a trial, that the joists are to be 2 by 10 in, 12 in on centers, that both the first-story and second-story ceilings are to be plastered, and that

only single flooring will be used in the second story and attic. We will assu that the attic-joists are to be 2 by 8 in, 16 in on centers, and that the width floor supported by the partition is 10 ft.

The second-floor area supported by a single joist is 12 in by 15 ft, or 15 sq The weight of the floor-joists per sq ft is 5 lb, of the plastered ceiling 10 lb a of the flooring 3 lb, making the dead load per sq ft 18 lb. For the live or sup imposed load we should allow 40 lb and hence the load per square foot on ea second-floor joist due to the second floor and its load is 58 lb. As the flo area for a single joist is 15 sq ft the load from the second floor is 15 sq ft 58 lb per sq ft or 870 lb on each joist. We must now find what will be t load from the partition and attic-floor. The attic-floor and ceiling weigh abo 16 lb per sq ft, and 24 lb is a sufficient allowance for the live load. The weig per linear foot on the partition will therefore be 400 lb. A partition of 2 4-in studs, lathed and plastered on both sides, weighs about 20 lb per sq ft face; hence the partition itself weighs 180 lb per lin ft. The partition a attic-floor, therefore, bring a load of 580 lb on each second-floor joist, co CENTRATED at a point ONE-FOURTH of the span from the inner end of the joi To combine this concentrated load with the load from the second floor, must multiply the concentrated load by 1.5 (Table IV, page 632), which gi an equivalent distributed load of 870 lb. Adding this to the second-floor lo we have 1 740 lb as the total load for which each joist should be proportion From Table VIII, page 639, we find that the safe load for a 1 by 10-in spr joist of 15-ft span is 518 lb; hence the breadth of each joist should be equal 1 740/518 = 3.36 or about 3½ in. Deeper joists, therefore, must be used. we try 2 by 12-in joists, 12 in on centers, the safe load for a 1 by 12-in spr joist of 15-ft span is 747 lb. Hence the breadth is 1 755/747 = 2.35 or abo 2⅜ in, indicating 2⅜ by 12-in joists, 12 in on centers. If the fiber-stres assumed at 800 lb per sq in, the values of Table X, page 641, may be us This will give, for 2 by 12-in joists, 12 in on centers and 15-ft span, 854 lb the safe load for a 1 by 12-in joist; and 1 755/854 = about 2 in. The load p sq ft on each of these joists is 1 755/15 = 117 lb; and Tables XVI and XX pages 739 and 744, give 16 ft 6 in and 16 ft 1 in for the maximum s spans.

Example 3. It is required to determine the sizes of the girders and joists the floor shown in Fig. 3, all of the timbers being of long-leaf yellow pine, a the floor above being supported by posts and girders in the same way. T building is intended for lodging purposes, and the height of the story is 10 There is to be a double floor and the ceilings and partitions are to be plaster The floor-joists are to be spaced 16 in on centers. Average timber, poorly seasor

Solution. We will first determine the size of the common joists at *A*, call the span 24 ft. The floor-area supported by a single joist is 24 by 1⅓ ft, 32 sq ft.

From Table XIII or XXII, pages 737 and 742, for a 24-ft span, 2½ by 14 joists are probably required. We will allow 8¾ lb per sq ft for the weight joists and bridging (Table I, page 718), 10 for the ceiling and 6 for the floori making 24¾ lb per sq ft for the dead load. For the live load we will allow lb per sq ft. The load for which the joists should be proportioned is, th fore, 32 by 64¾ or 2 072 lb. We may use Table XII, page 643, to find maximum load for a 1 by 14-in joist of 24-ft span. The deflection-load give the table is 882 lb; hence the thickness of the joists must equal 2 072/88 2.35 or about 2⅜ in. Therefore 2½ by 14-in long-leaf yellow-pine joists, 16 on centers, may be used, but they should run full 2½ in thick. The jo at *B* (Fig. 3) have to support a partition, but as the span is much less, and

partition is quite near the end of the joists, it will be safe to make them of the same size as at *A*.

The joists at *C* (Fig. 3) have the same floor-load to support as at *A*, and in addition the weight of the partition, which is concentrated at one-third of the span from one support. As the partition is 10 ft high, 13⅓ sq ft of partition will be supported by each joist, the joists being 16 in on centers. Assuming 20 lb

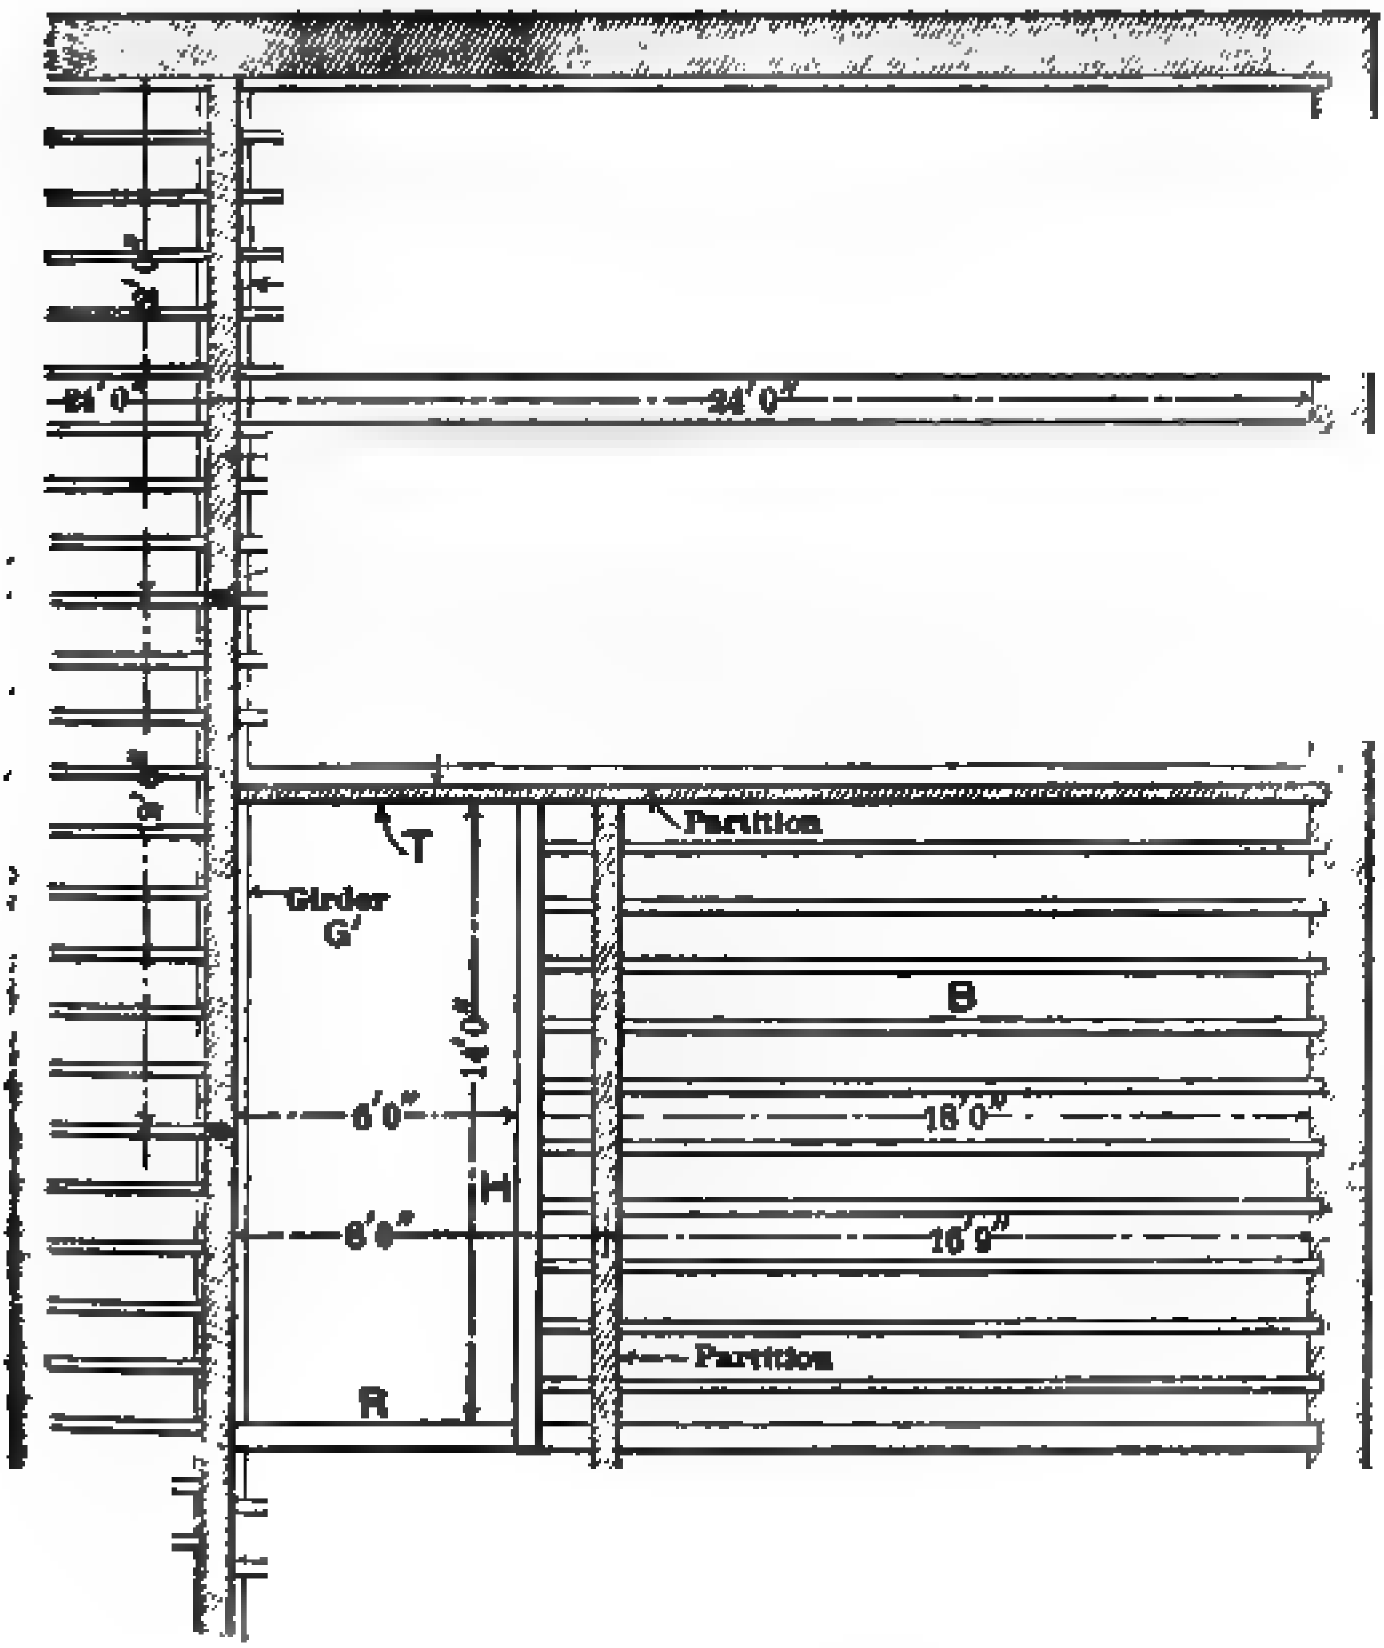

Fig. 3. Plan of Floor-framing Showing Partitions Above

sq ft of face as the weight of the partition, we have 267 lb as the weight the partition to be borne by each joist. To reduce this to an equivalent tributed load, we should multiply by 1.78 (Table IV, page 632), which gives lb. The joists at *C*, therefore, should be proportioned to a uniformly tributed load of 2 072 + 468 = 2 540 lb, which requires 14-in joists, 2.88 in r, say, 3 by 14-in joists.

The Header. We will next determine the required breadth for the head H (Fig. 3), the depth being necessarily 14 in, the same as for the joists.

The header is 14 ft long and must support the floor half-way to the wall, a floor-area of 14 by 9 ft, or 126 sq ft. Multiplying this area by 64¾ lb, t weight per square foot, we have 8 159 lb, the total floor-load to be support to which must be added a certain percentage of the partition. The portion the partition supported by the header is (14 ft − 1 ft 4 in) = 12 ft 8 in long a 10 ft high, and will weigh about 20 lb per sq ft of face, or a total of 2 532 As the partition is one-ninth of the span from the header, eight-ninths of weight will be supported by the header and one-ninth by the wall. Eight-nin of 2 532 is 2 251 lb, which, added to the floor-load, makes a total load the header of 10 410 lb. From Table XII, page 643, we find that the s load for a 1 by 14-in beam of long-leaf yellow pine, 14-ft span, is 1 867 lb; he it will require a breadth of 10 410/1 867 = 5.58 in. If the tail-beams are fram into the header, it should be thicker to allow for the weakening effects of t framing; so that, in this case, the header should be at least 6 by 14 in in act cross-section, before any framing is done.

The Trimmers. We will next consider the trimmer, T (Fig. 3). T beam has four loads: (1) a distributed floor-load; (2) a distributed load fr the partition above; (3) one-half the load on the header H; (4) and a sm direct load from the longitudinal partition.

(1) The strip of floor supported by the trimmer will be about 12 in wide a 24 ft long, and will weigh 64¾ lb per sq ft × 24 sq ft = 1 554 lb.

(2) The partition above will weigh 10 × 24 ft × 20 lb per sq ft = 4 800 lb

(3) One-half of the load on H is 10 410/2 = 5 205 lb. As this is concentra at one-fourth the span from the support, we must multiply it by 1.5 (Table page 632) to obtain the equivalent distributed load, which then becor 5 205 × 1.5 = 7 808 lb.

(4) About 8 in of the longitudinal partition must be supported by the trimm and this will weigh 10 × ⅔ ft × 20 lb per sq ft = 133 lb. As it is concentra at one-third the span from the support, we must multiply by 1.78 (Table page 632) to obtain the equivalent distributed load, which then becor 133 × 1.78 = 237 lb.

The total load for which the trimmer must be computed will be, therefore

(1) From the floor	1 554 lb
(2) From the partition above	4 800 lb
(3) From the header	7 808 lb
(4) From the longitudinal partition	237 lb
Total	14 399 lb

The trimmer should be of the same depth as the joists, 14 in. From Ta XII, page 643, we find that a 1 by 14-in long-leaf yellow-pine beam of 2 span will safely support 882 lb and not cause a deflection of more than 1⁄360 the span. Hence, the breadth of the trimmer would be 14 399/882 = 16.34 which is greater than the depth. This would suggest the substitution of a s I beam of proper size or the use of a deeper wooden beam, such as an 11 by 1 a 12 by 16-in beam. If the deflection of the wooden beam is not taken i account, the strength-value, 1 090 lb of Table XII, page 643, may be u giving 14 399/1 090 = 13.21 in as the width of the beam. This would ag with the former New York Code for strength. If the flexure fiber-stre taken at 1 300 lb per sq in, permitted by the Chicago code, Table XIII, p 644, may be used, giving 14 399/1 179 = 12.21 in for the width of the trimr

h 800 lb per sq in is taken for S, Table XV, page 646, is used, giving 14 399/ 633 = 8.81 in for the width. Hence, the architect will be governed by laws ities, or by engineering judgment or experience elsewhere, and this applies the joists as well as to the girders. If wooden trimmers are used, they should hung in beam-hangers (see last part of this chapter). The load on the trim- r, R, will be the same as on the trimmer, T, except for the cross-partition. ducting the weight of this partition, we have 14 399 − 4 800 = 9 599 lb for e equivalent distributed load on R, which, from Table XII, page 643, gives, for e required breadth 10.88 in or 8.8 in, depending upon whether the deflection or is not considered. Other variations in the required width of a 14-in oden girder will result from the use of other fiber-stresses.

The Girders. The floor-area supported by the girder, G (Fig. 3), is equal to by 24 ft, or 288 sq ft. As a general rule, it will be safe in estimating the live d on girders to take only 85% of the load assumed for the floor-beams, be- use there will always be some portion of the floor supported by the girder that not loaded, and probably other portions that will not be loaded up to the sumed load. Hence, the live load would be 85% of 40 lb, or 34 lb. The d load of the floor and ceiling will be about 25 lb, and the girder itself will gh between 1 and 2 lb per sq ft, say 2 lb per sq ft of floor, more, so that we l use 61 lb per sq ft for the total floor-load on this girder. As girder G sup- rts 288 sq ft, this will be equivalent to 17 568 lb. The girder supports, also, partition, 9 ft high, above, which will weigh 12 × 9 × 20 = 2 160 lb. The total d for which the girder should be proportioned is, therefore, 19 728 lb. As- ming 14 in for the depth of the girder, we find from Table XII, page 643, t the safe load for a 1 by 14-in long-leaf yellow-pine beam of 12-ft span is 867 lb; hence the breadth of girder, G, should be 19 728/1 867 = 10.56 in and 11 by 14-in girder could be used.

The girder, G' (Fig. 3), supports a floor-area at the left of 12 × 12 = 144 sq ft, ich represents a distributed load of 8 784 lb. On the right side of the girder re is a strip of floor 40 in wide by 12 ft long (8 in of the floor being included the load on T) which will weigh 2 440 lb. This may be considered as a con- trated load applied 20 in, or one-seventh the span, from the end of the der, in which case the effect of the load is practically the same as if the load re distributed. The load coming upon girder G' from T will equal one-half e actual distributed load on T, plus three-eighths (½ of ¾) of the load on H. e load on H we found to be 10 410 lb, and three-eighths of this is about 00 lb. The actual distributed load on T we found to be 1 554 + 4 800 = 54 lb, and one-half of this is 3 177 lb. Hence the trimmer, T, transmits a d of 3 900 + 3 177 = 7 077 lb to the girder, which must be considered as a centrated load applied at one-third the span from the support, and hence we t multiply it by 1.78 (Table IV, page 632) to obtain the equivalent dis- uted load, which gives 12 597 lb.

The load for which the girder, G' (Fig. 3), should be computed will be

From the floor at the left	8 784 lb
From the floor at the right	2 440 lb
From the trimmer, T	12 597 lb
From the partition above	2 160 lb
Total	25 981 lb

om Table XII, page 643, we find that this load will require a (13.9 by) 14 by 14-in girder. For this floor, therefore, the requirements, if -leaf yellow pine is used, and if the maximum flexure fiber-stress, S, is

taken at 1 200 lb per sq in (a conservative value for non-ideal conditio for example) and the modulus of elasticity, E, at 1 500 000 lb per sq in, are follows: an 11 by 14-in girder at G; a 14 by 14-in girder at G'; an 11 by 16, or by 16-in wooden beam or a steel I beam for the trimmer, T; an 11 by 14 beam for the trimmer, R; a 6 by 14-in beam for the header, H; 2½ by 14 joists at A and B; and 3 by 14-in joists at C. For these stress-requireme the architect might decide to use steel I beams for girders G, G', etc., and the trimmers, T and R. For S, 1300, Table XIII, page 644, may be used long-leaf yellow pine; for S, 1500 lb per sq in, Table XIV, page 645; for a fib stress, S, of 1800 lb per sq in, Table XV, page 646; and for S equal to 1600 per sq in. Table XII, page 643, with the strength-values increased one-thi Of course, the sizes of the timbers are diminished as the assumed safe fib stresses are increased.

This example illustrates nearly all of the computations that are required determine the sizes of the joists and special beams or girders in any ordina floor-construction. The method of computation is the same for any flo load, the only difference being that the greater the live load assumed the grea will be the loads for which the beams must be proportioned. As will be se the most laborious computations are those for beams which receive loads fr different sources, and it will generally be found that the weakest portions any particular floor are the headers, trimmers and girders, and the beams wh support partitions.

The Strength of Mill-Floors. The beams and girders for mill-flo should be computed by the same general method illustrated in the forego examples, involving, (1) the determination of the loads on the beams girders and, (2) the sizes of the beams and girders required to support su loads.

Required Thickness of Plank Flooring. The thickness of the plank flo ing in mill construction may be determined by formulas (1) and (2):

$$\left.\begin{array}{r}\text{Thickness of plank in in}\\ \text{required for strength}\end{array}\right\} = \sqrt{\frac{\text{weight per sq ft} \times l^2}{24 \times A}}$$

$$\left.\begin{array}{r}\text{Thickness of plank in in}\\ \text{required for stiffness}\end{array}\right\} = \sqrt[3]{\frac{\text{weight per sq ft} \times l^3}{19.2 \times e_1}}$$

In these formulas, l is the span in feet, from center to center of beams, A constants for strength (page 628), and e_1 the constant for stiffness (page 664)

When the planks are connected by ¾-in splines, and extend over two sp Formula (1) may be used. If the planks are in single lengths from beam to be or are not splined, then Formula (2) should be used.

Tables IV to XI,* inclusive, show the safe loads for plank flooring of diffe woods, thicknesses and spans, derived from the formulas for strength and stiffn the values in the first horizontal line in the case of each thickness of pl

* Tables VIII to XI, inclusive, were calculated by Mr. F. E. Kidder and are reta from the preceding edition of the Pocket-Book. Tables IV to VII, inclusive, are a to conform to the most conservative fiber-stresses of the building codes and of the c chapters of the new edition. In the judgment of many constructors the higher valu Tables VIII to XI are safe when more favorable conditions of quality and dryne materials prevail. In using any of the tables, care must be taken to notice whe or not the safe loads given include the weight of the flooring itself. In the revisio this chapter the author is indebted to Professor F. H. Safford, of the University of P sylvania, for the computations required for the new Tables IV to VII and for the chec of Tables VIII to XI.

[illegible]ting the loads given by the formula for strength and the figures in the [illegible]ond line those given by the formula for stiffness. The span is supposed to be [illegible]sured from center to center of beams. The values given by the formula for [illegible]ngth should be considered safe only for splined floors and where the planks [illegible] continuous over at least two spans. If the thickness of the planks falls [illegible]t ¼ or even ⅛ in from the dimensions given, the safe loads must be mate-[illegible]ly reduced.

[illegible] Table IV, the modulus of elasticity, E, on which e_1 in the stiffness-formula [illegible]nds, is 1 500 000 lb per sq in, and the safe fiber-stress, S, on which the [illegible]tant for strength, A, depends, is 1 200 lb per sq in, A being 67. The safe [illegible]s given are within the requirements of all cities for strength and stiffness for [illegible]-leaf yellow pine, and of all cities for Douglas fir.

[illegible] Table V, E is 1 200 000 lb per sq in, S, 1 000 lb per sq in, and A is 56. [illegible] loads given satisfy the requirements of Chicago and of most other cities [illegible]strength for short-leaf yellow pine. The values given for stiffness, also, are [illegible]mmended for this wood.

[illegible] Table VI, E is 1 200 000 lb per sq in, S, 800 lb per sq in, and A is 44. [illegible] loads given satisfy the requirements of all cities for strength, for spruce, [illegible]ay pine and white pine, and the values given for stiffness, also, are [illegible]mmended for spruce. For Norway pine, $E = 1\ 100\ 000$ lb per sq in may [illegible]ed.

[illegible] Table VII, E is 1 000 000 lb per sq in, S, 700 lb per sq in, and A is 39. [illegible] loads given for strength can be used for any woods of that safe fiber-[illegible], and the loads for stiffness are recommended for white pine.

[illegible] Tables VIII, IX, X and XI, the safe loads are calculated from still other [illegible]s of S, A, E and e_1, indicated with each table, and may be used by those [illegible] wish to assume larger safe values for the strength and stiffness-factors [illegible]es where there are no restrictions from building laws. For any other values [illegible] or e_1 required, such values must be inserted in Formula (1) or (2) and the [illegible]nesses of the planks determined or the safe load determined for any given [illegible]ness of planks.

[illegible]te. It is to be noted that for ideal conditions and commercially dry lum-[illegible] protected from moisture, and when there is no impact, the given fiber-stresses [illegible]lexure may be increased from 30 to 40%. (See, also, important notes on [illegible]s 628, 637 and 647 regarding stresses in and loads on wooden beams.)

Tables for the Maximum Span of Floor-Joists. As the timbers commo used for floor-joists are sawed to regular sizes and are usually spaced eithe or 16 in on centers, it is practicable to show by means of tables the sizes of jo required to support given loads with given spans and spacings. Tables gi the MAXIMUM SAFE SPANS are the most convenient for general use, and the foll ing tables have accordingly been prepared. They show at a glance the m imum spans for which different sizes of floor-joists and ceiling-joists shoul used for different loads and spacings, and it is believed that they will be fo applicable to most buildings in which wooden floor-joists are used. By kno the size of a room and the purpose for which it is to be used, the sizes of floor-joists required can be determined at a glance. Incidentally the ta show, also, the kind of wood most economical to use. If, owing to the r being irregular in shape, the joists must be of different lengths, the spacin thickness of the joists may be varied, so that the same depth may be throughout.

Precautions Required in Using Tables. The precautions necessary in u these tables are in regard to the superimposed loads and the ACTUAL SIZE the timbers. The TOTAL LOADS for which the maximum spans have been puted are given at the head of each table. The actual weight of the (joists, flooring, plastering and deafening, if any) subtracted from the total will give the SUPERIMPOSED LOAD, that is, the load which the floor is expecte carry. If the ACTUAL SIZES of the joists are less than the NOMINAL DIMENSI the spans or spacings must be reduced from those given in the tables, an the STOCK SIZES of joists generally run from ¼ in to ⅜ in scant of the NOM DIMENSIONS, this fact should always be taken into account when determi upon the sizes of joists. In this connection it will be convenient to reme that 2-in joists, spaced 16 in on centers, have the same strength as 1½-in j 12 in on centers. A reduction should also be made for any CUTTING OF JOISTS that may be required. No allowance has been made for PARTITIONS when they are to be supported by the floor-joists, additional joists shou used or the span reduced according to the relative direction or position o partitions and joists.

Tables XII to XX. Tables XII to XVI, inclusive, were computed by FORMULA FOR STIFFNESS (Chapter XVI, page 636 and Chapter XVIII, pages on the assumption that the deflection should not exceed 1/40 in per foot of They are based on the values of E (the modulus of elasticity) recommende F. E. Kidder. Tables XVII to XX, inclusive, were computed by the FOR FOR STRENGTH (Chapter XVI, page 635), and values for S (the safe fiber-s recommended by Mr. Kidder. The spans given in Tables XII to XX, sive, come within the requirements of the Buffalo and Denver building and Tables XII, XIV, XV, XVI and XVII comply with the Chicago la very nearly with the New York law; but to comply with the Boston reduction of about one-sixth must be made from the spans given (1914).*

Tables XXI to XXIX † inclusive, were computed for reduced values of E modulus of elasticity,) S (the fiber-stress for flexure) and A (the constan flexural strength) in the formulas used, these values agreeing generally wi stresses throughout the revised handbook. Of these new tables, also, T XXI to XXV, inclusive, were computed by the FORMULA FOR STIFFNESS Tables XXVI to XXIX, inclusive, by the FORMULA FOR STRENGTH.

* Building Codes are frequently revised and must be consulted.

† In the revision of this chapter the author is indebted to Mr. A. T. North, M. A C. E., for valuable assistance in the computations required for the new Tables X XXIX.
